

# CMS32L032 Reference Manual

Low power 32-bit microcontroller based on ARM® Cortex®-M0+

V1.0.3

Please note the following CMS IP policy

- \* China Micro Semicon (Shenzhen) Co., Ltd. (hereinafter referred to as the Company) has applied for a patent and enjoys absolute legal rights and interests. The patent rights related to the Company's MCUs or other products have not been authorized to be licensed, and any company, organization or individual who infringes the Company's patent rights through improper means will take all possible legal actions to curb the infringer's improper infringement and recover the losses suffered by the Company as a result of the infringement or the illegal benefits obtained by the infringer.
- \*The name and logo of China Micro Semicon (Shenzhen) Co., Ltd. are registered trademarks of the Company.
- \*The Company reserves the right to further explain the reliability, functionality and design improvements of the products in the data sheet. However, the Company is not responsible for the use of the Specification Contents. The applications mentioned herein are for illustrative purposes only and the Company does not warrant and does not represent that these applications can be applied without further modification, nor does it recommend that its products be used in places that may cause harm to persons due to malfunction or other reasons. The Company's products are not licensed for lifesaving, life-sustaining devices or systems as critical devices. The Company reserves the right to modify the product without prior notice, please refer to the official website www.mcu.com.cn for the latest information.

#### **Documentation Instructions**

This manual is a <u>technical reference manual</u> for the CMS32L032 microcontroller product. The <u>technical reference manual</u> is the application instruction material on how to use this series of products, including the structure, function description, working mode and register configuration of each functional module.

The <u>technical reference manual</u> is a description of all functional modules of this series of products. If you want to know the feature description of the product (that is, the functional configuration), you can refer to the respective data sheet.

The data sheet information is as follows:

CMS32L032xx: CMS32L032\_datasheet\_Vx.x.x. pdf

Usually in the early stage of chip selection, you shall first check the <u>data sheet</u> to evaluate whether the product can meet the functional requirements of the design; after basically selecting the required product, you need to check the <u>technical reference manual</u> to determine whether the working mode of each functional module does meet the requirement; When determining the selection and entering the programming design stage, you need to read the <u>technical reference manual</u> in detail to understand the specific implementation and register configuration of each function. Refer to the <u>data sheet</u> for information on voltages, currents, drive capabilities, and pin assignments when designing hardware.

For a detailed description of the Cortex-M0+ core, SysTick timer and NVIC, please refer to the respective ARM documents.

### Contents

| Documentation Instructions  | 2  |
|---|----|
| Chapter 1 CPU   | 13 |
| 1.1 Overview  | 13 |
| 1.2 Cortex-M0+ core features  | 13 |
| 1.3 Debugging features  | 13 |
| 1.4 SWD interface pins  | 15 |
| 1.5 ARM reference document  | 16 |
| Chapter 2 Port Function   | 17 |
| 2.1 Port function   | 17 |
| 2.2 Port multiplexing function  | 17 |
| 2.3 Registers for controlling port functions                            | 18 |
| 2.3.1 Port mode register (PMxx)   | 21 |
| 2.3.2 Port register (Pxx)   | 22 |
| 2.3.3 Port set control register (PSETxx)                                |    |
| 2.3.4 Port clear control register (PCLRxx)                              | 24 |
| 2.3.5 Pull-up resistor selection register (PUxx)                        | 25 |
| 2.3.6 Pull-down resistor selection register (PDxx)                      | 26 |
| 2.3.7 Port output mode register (POMxx)                                 | 27 |
| 2.3.8 Port mode control register (PMCxx)                                | 28 |
| 2.3.9 Port readback register (PREADxx)                                  |    |
| 2.3.10 Port multiplexing function configuration register (PxxCFG)       |    |
| 2.3.11 Description of the special function port RESINB                  | 31 |
| Chapter 3 System Architecture   | 32 |
| 3.1 Overview  | 32 |
| 3.2 System address partitioning   | 33 |
| Chapter 4 Clock Generation Circuit                                      | 35 |
| 4.1 Function of clock generation circuit                                | 35 |
| 4.2 Configuration of clock generation circuit                           |    |
| 4.3 Registers for controlling clock generation circuit                  | 40 |
| 4.3.1 Clock operation mode control register (CMC)                       | 40 |
| 4.3.2 System clock control register (CKC)                               | 42 |
| 4.3.3 Clock operation status control register (CSC)                     | 43 |
| 4.3.4 Oscillation stabilization time counter status register (OSTC)     | 45 |
| 4.3.5 Oscillation stabilization time select register (OSTS)             | 47 |
| 4.3.6 Peripheral enable registers 0, 1 (PER0, PER1)                     | 49 |
| 4.3.7 Subsystem clock supply mode control register (OSMC)               | 53 |
| 4.3.8 High-speed on-chip oscillator frequency select register (HOCODIV) | 54 |
| 4.3.9 High-speed on-chip oscillator trimming register (HIOTRM)          | 55 |
| 4.3.10Subsystem clock select register (SUBCKSEL)                        | 56 |
| 4.3.11 Power mode control protection register (PMUKEY)                  | 57 |
| 4.3.12 Power mode control register (PMUCTL)                             | 57 |
| 4.4 System clock oscillation circuit                                    |    |
| 4.4.1 X1 oscillation circuit  |    |
| 4.4.2 XT1 oscillation circuit   | 59 |

| 4.4.3   | High-speed on-chip oscillator   | 62  |
|---------|---|-----|
| 4.4.4   | Low-speed on-chip oscillator  | 62  |
| 4.5 O   | peration of clock generation circuit  | 63  |
| 4.6 CI  | ock control   | 65  |
| 4.6.1   | Example of setting up a high-speed on-chip oscillator                           | 65  |
| 4.6.2   | Example of setting X1 oscillation circuit                                       | 67  |
| 4.6.3   | Example of controlling XT1 oscillation clock                                    | 68  |
| 4.6.4   | CPU clock status transition diagram   | 69  |
| 4.6.5   | Conditions before CPU clock transfer and post-transfer processing               | 75  |
| 4.6.6   | Time required to switch CPU clock and main system clock                         | 77  |
| 4.6.7   | Conditions before clock oscillation is stopped                                  | 78  |
| 4.7 Hi  | gh-speed on-chip oscillation correction   | 79  |
| 4.7.1   | High-speed on-chip oscillation self-adjustment function                         | 79  |
| 4.7.2   | Description of register   | 80  |
| 4.7.3   | Description of operation  | 81  |
| 4.7.4   | Usage notes   | 85  |
| Chanter | 5 General-Purpose Timer Unit Timer4   | 86  |
|         |   |     |
|         | Inction of general-purpose timer unit   |     |
|         | Independent channel operation function  |     |
|         | Multi-channel linkage operation functions                                       |     |
|         | 8-bit timer operation function (channels 1 and 3 of unit 0 only)                |     |
|         | LIN-bus supporting function (channel 3 of unit 0 only)                          |     |
|         | ructure of general-purpose timer unit   |     |
|         | Register list of general-purpose timer unit 0                                   |     |
|         | Register list of general-purpose timer unit 1                                   |     |
|         | Timer count register mn (TCRmn)   |     |
|         | Timer data register mn (TDRmn)  |     |
|         | egisters for controlling general-purpose timer unit                             |     |
|         | Peripheral enable register 0 (PER0)   |     |
|         | Timer clock select register m (TPSm)  |     |
|         | Timer mode register mn (TMRmn)  |     |
|         | Timer status register mn (TSRmn)  |     |
|         | Timer channel enable status register m (TEm)                                    |     |
|         | Timer channel start register m (TSm)  |     |
|         | Timer channel stop register m (TTM)   |     |
|         | Timer input output select register (TIOS0)                                      |     |
|         | Timer output enable register m (TOEm)   |     |
|         | Timer output register m (TOm)   |     |
|         | Timer output level register m (TOLm)  |     |
|         | Timer output mode register m (TOMm)   |     |
|         | Noise filter enable register 1 (NFEN1)  |     |
|         | Noise filter enable register 2 (NFEN2)  |     |
|         | Registers controlling port functions of timer input/output pins                 |     |
|         | sic rules of general-purpose timer unit   |     |
|         | Basic rules of multi-channel linkage operation function                         |     |
|         | Basic rules of 8-bit timer operation function (channels 1 and 3 of unit 0 only) |     |
| 5.5 O   | peration of counter   | 124 |

|   | 1 Count clock (F <sub>TCLK</sub> )   | 124   |
|---|--|---|
| 5.5.  | 2 Start timing of counter  | 126   |
| 5.5.  | 3 Operation of counter   | 127   |
| 5.6   | Channel output (TOmn pin) control  | 132   |
| 5.6.  | 1 TOmn pin output circuit configuration  | 132   |
| 5.6.  | 2 TOmn pin output setting  | 133   |
| 5.6.  | 3 Cautions for channel output operation  | 134   |
| 5.6.  | 4 One-time operation of TOmn bit   | 139   |
| 5.6.  | 5 Timer interrupt and TOmn pin output when counting starts   | 140   |
| 5.7   | Control of timer input (Tlmn)  | 141   |
| 5.7.  | 1 Structure of Tlmn pin input circuit  | 141   |
| 5.7.  | 2 Noise filter   | 142   |
| 5.7.  | 3 Cautions on channel input operation  | 143   |
| 5.8   | Independent channel operation function of general-purpose timer unit   | 144   |
| 5.8.  | 1 Operation as interval timer/square wave output   | 144   |
| 5.8.  | 2 Operation as external event counter  | 148   |
| 5.8.3   | 3 Operation as frequency divider   | 151   |
| 5.8.  | 4 Operation as input pulse interval measurement  | 154   |
| 5.8.  | 5 Operation as input signal high-/low-level width measurement  | 157   |
| 5.8.  | 6 Operation as delay counter   | 161   |
| 5.9   | Multi-channel linkage operation function for general purpose timer unit  | 164   |
| 5.9.  | 1 Operation as single trigger pulse output function  | 164   |
| 5.9.  | 2 Operation as PWM function  | 171   |
| 5.9.  | 3 Operation as multiple PWM output function  | 178   |

| Chapter 7 Real-Time Clock  | 201 |
|--|-----|
| 7.1 Function of real-time clock  | 201 |
| 7.2 Structure of real-time clock   | 201 |
| 7.3 Registers for controlling real-time clock  | 203 |
| 7.3.1 Peripheral enable register 0 (PER0)  | 204 |
| 7.3.2 Real-time clock selection register (RTCCL)   |     |
| 7.3.3 Real-time clock control register 0 (RTCC0)   | 206 |
| 7.3.4 Real-time clock control register 1 (RTCC1)   |     |
| 7.3.5 Clock error correction register (SUBCUD)   | 209 |
| 7.3.6 Second count register (SEC)  | 210 |
| 7.3.7 Minute count register (MIN)  |     |
| 7.3.8 Hour count register (HOUR)   |     |
| 7.3.9 Day count register (DAY)   |     |
| 7.3.10Week count register (WEEK)   |     |
| 7.3.11 Month count register (MONTH)  |     |
| 7.3.12Year count register (YEAR)   |     |
| 7.3.13Alarm minute register (ALARMWM)  |     |
| 7.3.14Alarm hour register (ALARMWH)  |     |
| 7.3.15Alarm week register (ALARMWW)  |     |
| 7.3.16Port mode register and port register   |     |
| 7.4 Operation of real-time clock   |     |
| 7.4.1 Start of real-time clock operation   |     |
| 7.4.2 Shifting to sleep mode after starting operation                                    |     |
| 7.4.3 Reading/writing real-time clock  |     |
| 7.4.4 Setting alarm of real-time clock   |     |
| 7.4.5 1Hz output of real-time clock  |     |
| 7.4.6 Example of clock error correction of real-time clock                               | 224 |
| Chapter 8 15-Bit Interval Timer  | 226 |
| 8.1 Function of 15-bit interval timer  | 226 |
| 8.2 Structure of 15-bit interval timer   | 226 |
| 8.3 Registers for controlling 15-bit interval timer                                      | 227 |
| 8.3.1 Peripheral enable register 0 (PER0)  | 227 |
| 8.3.2 Real-time clock selection register (RTCCL)   | 228 |
| 8.3.3 15-bit interval timer control register (ITMC)                                      | 229 |
| 8.4 Operation of 15-bit interval timer   | 230 |
| 8.4.1 Operation timing of 15-bit interval timer  | 230 |
| 8.4.2 Start of count operation and re-enter to sleep mode after returned from sleep mode | 231 |
| Chapter 9 Clock Output/Buzzer Output Controller  | 232 |
| 9.1 Function of clock output/buzzer output controller                                    |     |
| 9.2 Structure of clock output/buzzer output controller                                   |     |
| 9.3 Registers for controlling clock output/buzzer output controller                      |     |
| 9.3.1 Clock output select register n (CKSn)  |     |
| 9.3.2 Registers for controlling clock output/buzzer output port functions                |     |
| 9.4 Operation of clock output/buzzer output controller                                   |     |
| 9.4.1 Operation as output pin  |     |
| 9.5 Cautions for clock output/buzzer output controller                                   |     |
| 5.5 Gaadono for Glook Galpar Galpar Goriti Office III.                                   | 201 |

| Chapter 10 Watch Dog Timer   | 238 |
|--|-----|
| 10.1 Function of watchdog timer  | 238 |
| 10.2 Structure of watch dog timer  | 238 |
| 10.3 Registers for controlling watchdog timer                                  | 240 |
| 10.3.1Watchdog timer enable register (WDTE)                                    | 240 |
| 10.3.2LOCKUP control register (LOCKCTL) and its protection register (PRCR)     | 241 |
| 10.3.3WDTCFG configuration register (WDTCFG0/1/2/3)                            | 242 |
| 10.4 Operation of watchdog timer   | 243 |
| 10.4.1Operational control of watchdog timer                                    | 243 |
| 10.4.2Setting overflow time of watchdog timer                                  | 245 |
| 10.4.3 Setting window open period of watchdog timer                            | 246 |
| 10.4.4Setting watchdog timer interval interrupt                                | 247 |
| 10.4.5 Operation of watchdog timer during LOCKUP                               | 247 |
| 10.4.6 Operation of watchdog timer when WDTCFG is not configured               | 247 |
| Chapter 11 A/D Converter   | 248 |
| 11.1 Function of A/D converter   | 248 |
| 11.2 Registers for controlling A/D converter                                   | 250 |
| 11.2.1 Peripheral enable register 0 (PER0)                                     | 251 |
| 11.2.2 A/D converter mode register 0 (ADM0)                                    | 252 |
| 11.2.3 A/D converter mode register 1 (ADM1)                                    | 257 |
| 11.2.4 A/D converter mode register 2 (ADM2)                                    | 258 |
| 11.2.5 A/D converter trigger mode register (ADTRG)                             | 259 |
| 11.2.6 Analog input channel specification register (ADS)                       | 260 |
| 11.2.7 12-bit A/D conversion result register (ADCR)                            | 262 |
| 11.2.88-bit A/D conversion result register (ADCRH)                             | 263 |
| 11.2.9 Conversion result comparison upper limit setting register (ADUL)        | 263 |
| 11.2.10 Conversion result comparison lower limit setting register (ADLL)       | 264 |
| 11.2.11 A/D converter sampling time control register (ADNSMP)                  | 264 |
| 11.2.12 Registers for controlling analog input port function                   | 264 |
| 11.3 Input voltage and conversion results                                      | 265 |
| 11.4 Operation mode of A/D converter   | 266 |
| 11.4.1 Software trigger mode (select mode, sequential conversion mode)         | 266 |
| 11.4.2 Software trigger mode (select mode, single conversion mode)             | 267 |
| 11.4.3 Software trigger mode (scan mode, sequential conversion mode)           | 268 |
| 11.4.4 Software trigger mode (scan mode, single conversion mode)               | 269 |
| 11.4.5 Hardware trigger no-wait mode (select mode, sequential conversion mode) | 270 |
| 11.4.6 Hardware trigger no-wait mode (select mode, single conversion mode)     | 271 |
| 11.4.7 Hardware trigger no-wait mode (scan mode, sequential conversion mode)   | 272 |
| 11.4.8 Hardware trigger no-wait mode (scan mode, single conversion mode)       | 273 |
| 11.4.9 Hardware trigger wait mode (select mode, sequential conversion mode)    | 274 |
| 11.4.10 Hardware trigger wait mode (select mode, single conversion mode)       | 275 |
| 11.4.11 Hardware trigger wait mode (scan mode, sequential conversion mode)     | 276 |
| 11.4.12 Hardware trigger wait mode (scan mode, single conversion mode)         | 277 |
| 11.5 A/D converter setup flowchart   | 278 |
| 11.5.1 Setting up software trigger mode  | 278 |
| 11.5.2 Setting up hardware trigger no-wait mode                                | 279 |
| 11.5.3 Setting up hardware trigger wait mode                                   | 280 |

| Chapter 12 General-Purpose Serial Communication Unit   | 281 |
|--|-----|
| 12.1 Function of general-purpose serial communication unit   | 282 |
| 12.1.13-wire serial I/O (SSPI00, SSPI01, SSPI10, SSPI11)   |     |
| 12.1.2UART (UART0, UART1)  | 283 |
| 12.2 Structure of general-purpose serial communication unit  | 284 |
| 12.2.1Shift register   | 286 |
| 12.2.2Serial data register mn (SDRmn)  | 286 |
| 12.3 Registers for controlling general-purpose serial communication unit                             | 288 |
| 12.3.1Peripheral enable register 0 (PER0)  | 290 |
| 12.3.2Serial clock select register m (SPSm)  | 291 |
| 12.3.3Serial mode register mn (SMRmn)  | 292 |
| 12.3.4Serial communication run setting register mn (SCRmn)   | 294 |
| 12.3.5Serial data register mn (SDRmn)  | 297 |
| 12.3.6Serial flag clear trigger register mn(SIRmn)   | 298 |
| 12.3.7 Serial status register mn (SSRmn)   | 299 |
| 12.3.8 Serial channel start register m(SSm)  | 301 |
| 12.3.9 Serial channel stop register m(STm)   | 302 |
| 12.3.10 Serial channel enable status register m (SEm)  |     |
| 12.3.11 Serial output enable register m (SOEm)   | 304 |
| 12.3.12 Serial output register m (SOm)   |     |
| 12.3.13 Serial output level register m (SOLm)  | 306 |
| 12.3.14 Input switching control register (ISC)   |     |
| 12.3.15 Noise filter enable register 0 (NFEN0)   |     |
| 12.3.16 Registers controlling port functions of serial input/output pins                             |     |
| 12.4 Operation stop mode   |     |
| 12.4.1Stopping the operation by units  |     |
| 12.4.2Stopping the operation by channels   |     |
| 12.5 3-wire serial I/O (SSPI00, SSPI01, SSPI10, SSPI11) communication                                |     |
| 12.5.1Master transmission  |     |
| 12.5.2Master reception   |     |
| 12.5.3Master transmission and reception  |     |
| 12.5.4 Slave transmission  |     |
| 12.5.5Slave reception  |     |
| 12.5.6 Slave transmission and reception  |     |
| 12.5.7 Calculation of transmission clock frequency   |     |
| 12.5.8 Procedure for handling errors during 3-wire serial I/O communication (SSPI00, SSPI01, SSPI11) |     |
| 12.6 Operation of clock-synchronous serial communication with slave selection input function         | 364 |
| 12.6.1Slave transmission   | 367 |
| 12.6.2Slave reception  | 377 |
| 12.6.3 Slave transmission and reception  | 384 |
| 12.6.4 Calculation of transmission clock frequency   | 394 |
| 12.6.5 Procedure for handling errors during clock-synchronous serial communication with t            |     |
| selection input function   |     |
| 12.7 Operation of UART (UART0~UART1) communication   |     |
| 12.7.1UART transmission  |     |
| 12.7.2UART reception   | 405 |

| 12.7.3Calculation of baud rate  | 412 |
|---|-----|
| 12.7.4Handling steps when an error occurs during UART (UART0~UART1) communication | 416 |
| 12.8 Operation of LIN communication   | 417 |
| 12.8.1LIN transmission  |     |
| 12.8.2LIN reception   | 420 |
| Chapter 13 Serial Interface SPI   | 425 |
| 13.1 Function of serial interface SPI   | 425 |
| 13.2 Structure of serial interface SPI  | 425 |
| 13.3 Registers for controlling serial interface SPI                               | 426 |
| 13.3.1Peripheral enable register 0 (PER0)   | 426 |
| 13.3.2SPI operation mode register (SPIM)  |     |
| 13.3.3SPI clock selection register (SPIC)   | 428 |
| 13.3.4Transmit buffer register (SDRO)   |     |
| 13.3.5Receive buffer register (SDRI)  |     |
| 13.3.6 Registers controlling port functions of SPI pins                           |     |
| 13.4 Operation of serial interface SPI  |     |
| 13.4.1 Master tramission and reception  |     |
| 13.4.2 Master reception   |     |
| 13.4.3 Slave transmission and reception   |     |
| 13.4.4Slave reception   | 439 |
| Chapter 14 Serial Interface IICA  | 442 |
| 14.1 Function of serial interface IICA  |     |
| 14.2 Structure of serial interface IICA   |     |
| 14.3 Registers for controlling serial interface IICA                              |     |
| 14.3.1Peripheral enable register 0 (PER0)   |     |
| 14.3.2 IICA control register n0 (IICCTLn0)  |     |
| 14.3.3 IICA status register n(IICSn)  |     |
| 14.3.4 IICA flag register n(IICFn)  |     |
| 14.3.5IICA control register n1(IICCTLn1)  |     |
| 14.3.6 IICA low-level width setting register n(IICWLn)                            |     |
| 14.3.7 IICA high level width setting register n(IICWHn)                           |     |
| 14.3.8 Registers controlling port functions of IICA pins                          |     |
| 14.4 Function of I <sup>2</sup> C-bus mode  |     |
| 14.4.1Pin structure   |     |
| 14.4.2Setting transfer clock via IICWLn and IICWHn registers                      |     |
| 14.5 Definition and control method of I <sup>2</sup> C-bus                        |     |
| 14.5.1 Start condition  |     |
| 14.5.2Address   |     |
| 14.5.3Transfer direction specification  |     |
| 14.5.4Acknowledge (ACK)   |     |
| 14.5.5Stop condition  |     |
| 14.5.6Wait  |     |
| 14.5.7 Method of releasing wait state   |     |
| 14.5.8Generation timing and waiting control of interrupt requests (INTIICAn)      |     |
| 14.5.9Detection method for address matching                                       |     |
| 14.J. 10 LITOI UCICOLIOIT   | 470 |

| 14.5.11 Extension code  | 476 |
|---|-----|
| 14.5.12 Arbitration   | 477 |
| 14.5.13 Wake-up function  | 479 |
| 14.5.14 Communication reservation   | 482 |
| 14.5.15 Cautions  |     |
| 14.5.16 Communication operation   | 487 |
| 14.5.17 Timing of I <sup>2</sup> C interrupt request (INTIICAn) generation                          | 496 |
| 14.6 Timing diagram   | 516 |
| Chapter 15 Linkage Controller EVENTC  | 531 |
| 15.1 Function of EVENTC   | 531 |
| 15.2 Structure of EVENTC  | 531 |
| 15.3 Control registers  | 532 |
| 15.3.1Output target selection register n(ELSELRn) (n=00~12)   | 533 |
| 15.4 Operation of EVENTC  | 535 |
| Chapter 16 Interrupt Function   | 536 |
| 16.1 Types of interrupt functions   | 536 |
| 16.2 Interrupt sources and structures   |     |
| 16.3 Registers for controlling interrupt function   | 541 |
| 16.3.1 Interrupt request flag register (IF00~IF31)  |     |
| 16.3.2Interrupt mask flag register (MK00~MK31)  | 542 |
| 16.3.3External interrupt rising edge enable register (EGP0), External interrupt falling edge (EGN0) | •   |
| 16.4 Operation of interrupt handling  | 545 |
| 16.4.1Maskable interrupt request acknowledgment   | 545 |
| 16.4.2Non-maskable interrupt request acknowledgment   | 545 |
| Chapter 17 Key Interrupt Function   | 546 |
| 17.1 Function of key interrupt  | 546 |
| 17.2 Structure of key interrupt   | 547 |
| 17.3 Registers for controlling key interrupts   | 548 |
| 17.3.1Key return mode register (KRM)  | 548 |
| 17.3.2Port mode register (PMx)  | 548 |
| Chapter 18 Standby Function   | 549 |
| 18.1 Standby function   | 549 |
| 18.2 Sleep mode   |     |
| 18.2.1Setting of sleep mode   |     |
| 18.2.2Sleep mode release  |     |
| 18.3 Deep sleep mode  |     |
| 18.3.1 Setting of deep sleep mode   | 554 |
| 18.3.2Deep sleep mode release   | 556 |
| 18.4 Deep sleep mode with partial power down  | 557 |
| 18.4.1Setting of deep sleep mode with partial power down  | 557 |
| 18.4.2Release deep sleep mode with partial power down   | 560 |
| Chapter 19 Reset Function   | 561 |
| 19.1 Registers for confirming the reset source  | 566 |
| 19.1.1Reset control flag register (RESF)  |     |

| Chapter 20 Power-On Reset Circuit   | 568 |
|---|-----|
| 20.1 Function of power-on reset circuit                                     | 568 |
| 20.2 Structure of power-on reset circuit                                    | 569 |
| 20.3 Operation of power-on reset circuit                                    | 570 |
| Chapter 21 Voltage Detection Circuit  | 573 |
| 21.1 Function of voltage detection circuit                                  | 573 |
| 21.2 Structure of voltage detection circuit                                 |     |
| 21.3 Registers for controlling voltage detection circuit                    |     |
| 21.3.1Voltage detection register (LVIM)                                     |     |
| 21.3.2Voltage detection level register (LVIS)                               |     |
| 21.4 Operation of voltage detection circuit                                 |     |
| 21.4.1When used as reset mode   |     |
| 21.4.2When used as interrupt mode   |     |
| 21.5 Cautions for voltage detection circuits                                |     |
| -   |     |
| Chapter 22 Safety Function  |     |
| 22.1 Summary of safety functions  |     |
| 22.2 Registers used for safety functions                                    |     |
| 22.3 Operation of safety functions  |     |
| 22.3.2CRC operation function (general-purpose CRC)                          |     |
| 22.3.3SFR guard function  |     |
| 22.3.4Frequency detection function  |     |
| 22.3.5A/D test function   |     |
| 22.3.6 Digital output signal level detection function for input/output pins |     |
| 22.3.7Product unique identification register                                | 604 |
| Chapter 23 Temperature sensor   | 605 |
| 23.1 Function of temperature sensor   | 605 |
| 23.2 Temperature sensor register  |     |
| 23.2.1Temperature sensor calibration data register TSN25                    | 605 |
| 23.3 Instructions for using temperature sensor                              | 606 |
| Chapter 24 Option Bytes   | 607 |
| 24.1 Function of option bytes   | 607 |
| 24.1.1User option bytes (000C0H~000C2H)                                     | 607 |
| 24.1.2Flash data protection option bytes (000C3H, 500004H)                  | 608 |
| 24.2 Format of user option bytes  | 609 |
| 24.3 Format of flash data protection option bytes                           | 615 |
| Chapter 25 FLASH Control  | 616 |
| 25.1 FLASH control function description                                     | 616 |
| 25.2 Structure of FLASH memory  | 616 |
| 25.3 Registers for controlling FLASH  |     |
| 25.3.1Flash write protection register (FLPROT)                              |     |
| 25.3.2FLASH operation control register (FLOPMD1, FLOPMD2)                   |     |
| 25.3.3Flash erase control register (FLERMD)                                 |     |
| 25.3.4Flash status register (FLSTS)   | 619 |

| 25.3.5 Flash chip erase time control register (FLCERCNT)   | 619 |
|--|-----|
| 25.3.6 Flash sector erase time control register (FLSERCNT) | 620 |
| 25.3.7 Flash write time control register (FLPROCNT)        | 621 |
| 25.4 How to operate FLASH                                  | 622 |
| 25.4.1Sector erase   | 622 |
| 25.4.2Chip erase   | 623 |
| 25.4.3Word program   | 623 |
| 25.5 Flash read  | 623 |
| 25.6 Cautions for FLASH operation                          | 623 |
| Appendix Revision History                                  | 624 |

# **Chapter 1 CPU**

#### 1.1 Overview

This chapter provides a brief introduction to the features and debugging features of the ARM Cortex-M0+core. For details, please refer to the ARM related documentation.

#### 1.2 Cortex-M0+ core features

- ARM Cortex-M0+ processor is a 32-bit RISC core with a 2-stage pipeline that supports privileged and user modes
- 32-cycle hardware multiplier
- Nested vector interrupt controller (NVIC)
  - 1 non-maskable interrupt (NMI)
  - Support 32 maskable interrupt requests (IRQ)
  - 4 interrupt priority levels
- System Timer (SysTick) is a 24-bit countdown timer with a choice of F<sub>CLK</sub> or F<sub>IL</sub> count clock
- Vector table offset register (VTOR)
  - The software can write VTOR to relocate the vector table start address to a different location.
  - The default value of this register is 0x0000\_0000, the lower 8 bits are ignored for writing and zero for reading, which means the offset is 256 bytes aligned.

### 1.3 Debugging features

- 2-wire SWD debug interface
- Support for suspending, resuming and single-step execution of programs
- Access to the processor's core registers and special function registers
- 4 hardware breakpoints (BPU)
- Unlimited software breakpoints (BKPT instruction)
- 2 data observation points (DWT)
- Accessing memory while the core is executing

www.mcu.com.cn 13 / 624 Rev.1.0.3

Figure 1-1: Debug block diagram of Cortex-M0+

Notice: SWD does not work in deep sleep mode, please do debug operation in active and sleep mode.

www.mcu.com.cn 14 / 624 Rev.1.0.3

## 1.4 SWD interface pins

The 2 GPIOs of this product can be used as SWD interface pins, which exist in all packages.

Table 1-1: SWD debug port pins

| SWD port name | Debugging functions      | Pin assignment |
|---------------|--------------------------|----------------|
| SWCLK         | Serial clock             | P21/P37        |
| SWDIO         | Serial data input/output | P20/P36        |

When the SWD function is not used, SWD can be disabled by setting the debug stop control register (DBGSTOPCR).

| Address: 0x4001B004 |    |    | After reset: 00H |    |    | R/W |        |        |
|---------------------|----|----|------------------|----|----|-----|--------|--------|
| Bit No.             | 31 | 30 | 29               | 28 | 27 | 26  | 25     | 24     |
| DBGSTOPCR           | -  | -  | -                | -  | -  | -   | -      | SWDIS  |
| Default Value       | 0  | 0  | 0                | 0  | 0  | 0   | 0      | 0      |
| Bit No.             | 23 | 22 | 21               | 20 | 19 | 18  | 17     | 16     |
| DBGSTOPCR           | -  | -  | -                | -  | -  | -   | -      | -      |
| Default Value       | 0  | 0  | 0                | 0  | 0  | 0   | 0      | 0      |
| Bit No.             | 15 | 14 | 13               | 12 | 11 | 10  | 9      | 8      |
| DBGSTOPCR           | -  | -  | -                | -  | -  | -   | -      | -      |
| Default Value       | 0  | 0  | 0                | 0  | 0  | 0   | 0      | 0      |
| Bit No.             | 7  | 6  | 5                | 4  | 3  | 2   | 1      | 0      |
| DBGSTOPCR           | -  | -  | -                | -  | -  | -   | FRZEN1 | FRZEN0 |
| Default Value       | 0  | 0  | 0                | 0  | 0  | 0   | 0      | 0      |

| SWDIS | SWD debug interface status   |
|-------|--|
| 0     | Enable the SWD debug interface. P20/P36 cannot be used as GPIO (because ENO and DOUT of this IOBUF are controlled by the debugger at this time). |
| 1     | Disable the SWD debug interface. P20/P36 can be used as GPIO.  |

| FRZEN0 | When the debugger is connected and the CPU is in debug state (HALTED=1), the timer system peripheral module acts/stops Note1. |
|--------|---|
| 0      | Peripheral acts   |
| 1      | Peripheral stops  |

| FRZEN1 | When the debugger is connected and the CPU is in debug state (HALTED=1), the peripheral module of the communication system acts/stops Note2. |
|--------|--|
| 0      | Peripheral acts  |
| 1      | Peripheral stops   |

Note 1: The timer system peripheral module of this product includes: general-purpose timer unit Timer4

Note 2: The communication system peripheral module of this product includes: serial communication unit, serial IICA.

# **Chapter 2 Port Function**

### 2.1 Port function

See the <u>datasheet</u> for each product series.

## 2.2 Port multiplexing function

See the <u>datasheet</u> for each product series.

www.mcu.com.cn 17 / 624 Rev.1.0.3

## 2.3 Registers for controlling port functions

The port functions are controlled through the following registers.

- (1) Port mode register (PMxx)
- (2) Port register (Pxx)
- (3) Pull-up resistor selection register (PUxx)
- (4) Pull-down resistor selection register (PDxx)
- (5) Port output mode register (POMx)
- (6) Port mode control register (PMCxx)
- (7) Port set control register (PSETxx)
- (8) Port clear control register (PCLRxx)
- (9) Port status readback register (PREADxx)
- (10) Port output multiplexing configuration register (PxxCFG)

Table 2-1: PMxx, Pxx, PSETxx, PCLRxx, PUxx, PDxx, POMxx, PMCxx registers and their bits assigned to each product

|        |   |                  |                 |                 |                    | •                |                  |                   |                   |                 |      |      |

Note: Since this product supports arbitrary GPIO mapping for all digital functions, the corresponding functions in the above table and the value of PxxCFG need to correspond one to one.

#### Configuration description:

- (1) When using the port's multiplexing function, the port must be configured in digital mode (PMCxx=0).
- (2) When using the port's multiplexing function, the port must be configured in output mode (push-pull or open-drain) (PMxx=0).
- (3) When using the GPIO function or multiplexing function of P01, P02 ports, make sure that their X1 oscillation mode and external clock input mode are not turned on. Refer to section 4.3.
- (4) When using the GPIO function or multiplexing function of P12, P13 ports, make sure that their XT1 oscillation mode and external clock input mode are not turned on. Refer to section 4.3.

www.mcu.com.cn 20 / 624 Rev.1.0.3

### 2.3.1 Port mode register (PMxx)

When a port is used as a digital channel, this is the register that sets its input/output in bits. After a reset signal is generated, all ports default to the input state. When using a port pin as a multiplexing function, it must be set according to the register settings for the multiplexing function.

Register address = base address + offset address; the base address of PM register is 0x40040000, and the offset address is shown in the table below.

Table 2-3: Format of port mode register

| Symbol | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    | Offset address | After reset | R/W |
|--------|------|------|------|------|------|------|------|------|----------------|-------------|-----|
| PM0    | 1    | 1    | 1    | 1    | 1    | PM02 | PM01 | PM00 | 0x020          | FFH         | R/W |
|        |      |      |      |      |      |      |      |      | _              |             |     |

## 2.3.2 Port register (Pxx)

This is the register that sets the value of the port's output latch in bits. Reading this register in input mode gives the pin level, while reading it in output mode gives the value of the port's output latch. After a reset signal is generated, the value of these registers changes to "00H".

Register address = base address + offset address; the base address of Port register is 0x40040000, and the offset address is shown in the table below.

Table 2-4: Format of the port register

| Symbol | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   | Offset address | After reset | R/W |
|--------|-----|-----|-----|-----|-----|-----|-----|-----|----------------|-------------|-----|
| P0     | 0   | 0   | 0   | 0   | 0   | P02 | P01 | P00 | 0x000          | 00H         | R/W |
| P1     | 0   | 0   | 0   | 0   | P13 | P12 | P11 | P10 | 0x001          | 00H         | R/W |
| P2     | 0   | P26 | P25 | P24 | P23 | P22 | P21 | P20 | 0x002          | 00H         | R/W |

| Desc | m=0-                                 | ~3, n=0~7                          |
|------|--------------------------------------|------------------------------------|
| Pmn  | Control of output data (output mode) | Reading of input data (input mode) |
| 0    | The port outputs "0".                | Port input low level.              |
| 1    | The port outputs "1".                | Port input high level.             |

www.mcu.com.cn 22 / 624 Rev.1.0.3

### 2.3.3 Port set control register (PSETxx)

These are registers that reset the port output latch in bit units. The value of these registers changes to "00H" after a reset signal is generated.

Register address = base address + offset address; the base address of PSET register is 0x40040000, and the offset address is shown in the table below.

Table 2-5: Format of port set control register

| Symbol | 7      | 6      | 5      | 4      | 3      | 2      | 1      | 0      | Offset address | After reset | R/W |  |
|--------|--------|--------|--------|--------|--------|--------|--------|--------|----------------|-------------|-----|--|
| PSET0  | 0      | 0      | 0      | 0      | 0      | PSET02 | PSET01 | PSET00 | 0x070          | 00H         | W   |  |
|        |        |        |        |        |        |        |        |        |                |             |     |  |
| PSET1  | 0      | 0      | 0      | 0      | PSET13 | PSET12 | PSET11 | PSET10 | 0x071          | 00H         | W   |  |
|        |        |        |        |        |        |        |        |        |                |             |     |  |
| PSET2  | 0      | PSET26 | PSET25 | PSET24 | PSET23 | PSET22 | PSET21 | PSET20 | 0x072          | 00H         | W   |  |
|        |        |        |        |        |        |        |        |        |                |             |     |  |
| PSET3  | PSET37 | PSET36 | PSET35 | PSET34 | PSET33 | PSET32 | PSET31 | PSET30 | 0x073          | 00H         | W   |  |

| PSETmn | Setting control of Pmn pin (m=0~3, n=0~7) |
|--------|---|
| 0      | No operation                              |
| 1      | Set the corresponding Pmn to 1            |

www.mcu.com.cn 23 / 624 Rev.1.0.3

### 2.3.4 Port clear control register (PCLRxx)

This is the register to set the port output latch in bit units. After a reset signal is generated, the value of these registers becomes "00H".

Register address = base address + offset address; the base address of PCLR register is 0x40040000, and the offset address is shown in the table below.

Table 2-6: Format of port clear control register

| Symbol | 7      | 6      | 5      | 4      | 3      | 2      | 1      | 0      | Offset address | After reset | R/W |
|--------|--------|--------|--------|--------|--------|--------|--------|--------|----------------|-------------|-----|
| PCLR0  | 0      | 0      | 0      | 0      | 0      | PCLR02 | PCLR01 | PCLR00 | 0x080          | 00H         | W   |
|        |        |        |        |        |        |        |        |        |                |             |     |
| PCLR1  | 0      | 0      | 0      | 0      | PCLR13 | PCLR12 | PCLR11 | PCLR10 | 0x081          | 00H         | W   |
|        |        |        |        |        |        |        |        |        |                |             |     |
| PCLR2  | 0      | PCLR26 | PCLR25 | PCLR24 | PCLR23 | PCLR22 | PCLR21 | PCLR20 | 0x082          | 00H         | W   |
|        |        |        |        |        |        |        |        |        |                |             |     |
| PCLR3  | PCLR37 | PCLR36 | PCLR35 | PCLR34 | PCLR33 | PCLR32 | PCLR31 | PCLR30 | 0x083          | 00H         | W   |

| PCLRmn | Clear control of Pmn pin (m=0~3, n=0~7) |
|--------|---|
| 0      | No operation                            |
| 1      | Set the corresponding Pmn to 0          |

www.mcu.com.cn 24 / 624 Rev.1.0.3

#### 2.3.5 Pull-up resistor selection register (PUxx)

This is the internal pull-up resistor selection register. For pins configured for digital functions, internal pull-up resistors can be used in bits through the pull-up resistor selection register; pins set for analog functions do not connect internal pull-up resistors.

After generating the reset signal, the pull-up function of the four ports P00, P20, P21, P36, and P37 is turned on by default (the reset value of PU00, PU20, PU21, PU36, and P37 is "1"), and the pull-up function of the other ports is not turned on by default.

Register address = base address + offset address; the base address of PU register is 0x40040000, and the offset address is shown in the table below.

Table 2-7: Format of pull-up resistor selection register

| Symbol | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    | Offset address | After reset | R/W |
|--------|------|------|------|------|------|------|------|------|----------------|-------------|-----|
| PU0    | 0    | 0    | 0    | 0    | 0    | PU02 | PU01 | PU00 | 0x030          | 01H         | R/W |
|        |      |      |      |      |      |      |      |      |                |             |     |
| PU1    | 0    | 0    | 0    | 0    | 0    | 0    | PU11 | PU10 | 0x031          | 00H         | R/W |
|        |      |      |      |      |      |      |      |      |                |             |     |
| PU2    | 0    | PU26 | PU25 | PU24 | PU23 | PU22 | PU21 | PU20 | 0x032          | 03H         | R/W |
|        |      |      |      |      |      |      |      |      | _              |             |     |
| PU3    | PU37 | PU36 | PU35 | PU34 | PU33 | PU32 | PU31 | PU30 | 0x033          | C0H         | R/W |

| PUmn | Selection of internal pull-up resistor for Pmn pin (m=0~3, n=0~7) |
|------|---|
| 0    | No internal pull-up resistor is connected.                        |
| 1    | Connect the internal pull-up resistor.                            |

Notice: Ports P12 and P13 of this product do not support pull-up function, and must be connected to external pull-up resistors when used.

www.mcu.com.cn 25 / 624 Rev.1.0.3

#### 2.3.6 Pull-down resistor selection register (PDxx)

This is the internal pull-down resistor selection register. For pins configured for digital functions, internal pull-down resistors can be used in bits through the pull-down resistor selection register; pins set for analog functions do not connect internal pull-down resistors.

After a reset signal is generated, the value of the register changes to "00H".

Register address = base address + offset address; the base address of PD register is 0x40040000, and the offset address is shown in the table below.

Table 2-8: Format of pull-down resistor selection register

| Symbol | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    | Offset address | After reset | R/W |
|--------|------|------|------|------|------|------|------|------|----------------|-------------|-----|
| PD0    | 0    | 0    | 0    | 0    | 0    | PD02 | PD01 | 0    | 0x040          | 00H         | R/W |
|        |      |      |      |      |      |      |      |      | _              |             |     |
| PD1    | 0    | 0    | 0    | 0    | 0    | 0    | PD11 | PD10 | 0x041          | 00H         | R/W |

### 2.3.7 Port output mode register (POMxx)

This is a register that sets the output mode in bits. The pin selects the N-channel open drain output mode when communicating between devices.

After a reset signal is generated, the value of the register changes to "00H".

Register address = base address + offset address; the base address of POM register is 0x40040000, and the offset address is shown in the table below.

Table 2-9: Format of port output mode register

| Symbol | 7     | 6     | 5     | 4     | 3     | 2     | 1     | 0     | Offset address | After reset | R/W |
|--------|-------|-------|-------|-------|-------|-------|-------|-------|----------------|-------------|-----|
| POM0   | 0     | 0     | 0     | 0     | 0     | POM02 | POM01 | POM00 | 0x050          | 00H         | R/W |
|        |       |       |       |       |       |       |       | 1     | 1              |             |     |

#### 2.3.8 Port mode control register (PMCxx)

The PMC register sets the port in bits to be used as a digital input/output or as an analog channel.

After the reset signal is generated, P00, P01, P02, P20, P21, P36, P37 are used as digital channels by default (PMC00, PMC01, PMC02, PMC20, PMC21, PMC36, PMC37 reset values are "0"), and the other ports are used as analog channel by default.

Register address = base address + offset address; the base address of PMC register is 0x40040000, and the offset address is shown in the table below.

Table 2-10: Format of port mode control register

| Symbol | 7     | 6     | 5     | 4     | 3     | 2     | 1     | 0     | Offset address | After reset | R/W |
|--------|-------|-------|-------|-------|-------|-------|-------|-------|----------------|-------------|-----|
| PMC0   | 1     | 1     | 1     | 1     | 1     | PMC02 | PMC01 | PMC00 | 0x060          | F8H         | R/W |
|        |       |       |       |       |       |       |       |       |                |             |     |

### 2.3.9 Port readback register (PREADxx)

This is a read-only register that can be read to get the corresponding port level when the port is used as a digital GPIO.

Register address = base address + offset address; the base address of PREAD register is 0x40040000, and the offset address is shown in the table below.

| Symbol | 7       | 6       | 5       | 4       | 3       | 2       | 1       | 0       | Offset address | Reset value | R/W |
|--------|---------|---------|---------|---------|---------|---------|---------|---------|----------------|-------------|-----|
| PREAD0 |         |         |         |         |         | PREAD02 | PREAD01 | PREAD00 | 0x90           | xxxxH       | R   |
| PREAD1 |         |         |         |         | PREAD13 | PREAD12 | PREAD11 | PREAD10 | 0x91           | xxxxH       | R   |
| PREAD2 |         | PREAD26 | PREAD25 | PREAD24 | PREAD23 | PREAD22 | PREAD21 | PREAD20 | 0x92           | xxxxH       | R   |
| PREAD3 | PREAD37 | PREAD36 | PREAD35 | PREAD34 | PREAD33 | PREAD32 | PREAD31 | PREAD30 | 0x93           | xxxxH       | R   |

| PREADmn   | m=0~3, n=0~7                   |
|-----------|--------------------------------|
| FREADIIII | Digital output mode/input mode |
| 0         | Port is low                    |
| 1         | Port is high                   |

Remark: PREAD is only used for read operation and does not support write operation. Its read value after reset depends on the corresponding port level.

www.mcu.com.cn 29 / 624 Rev.1.0.3

### 2.3.10 Port multiplexing function configuration register (PxxCFG)

The port multiplexing function configuration register can map the output function of some peripheral modules to any port. If the reset value of the port multiplexing function configuration register is "00H", then the port is GPIO function by default.

Register address = base address + offset address; the base address of PxxCFG register is 0x40040800, and the offset address is shown in the table below.

Base address: 0x40040800

Table 2-11: Format of port multiplexing function configuration register

| Symbol         | 7      | 6      | 5      | 4      | 3      | 2      | 1      | 0      |
|----------------|--------|--------|--------|--------|--------|--------|--------|--------|
| P0xCFG         |        | -      | -      | -      | -      | P02CFG | P01CFG | P00CFG |
| Offset address | -      | -      | -      | -      | -      | 0x04   | 0x02   | 0x00   |
| P1xCFG         |        |        |        |        | P13CFG | P12CFG | P11CFG | P10CFG |
| Offset address |        |        |        |        | 0x16   | 0x14   | 0x12   | 0x10   |
| P2xCFG         |        | P26CFG | P25CFG | P24CFG | P23CFG | P22CFG | P21CFG | P20CFG |
| Offset address |        | 0x2c   | 0x2a   | 0x28   | 0x26   | 0x24   | 0x22   | 0x20   |
| P3xCFG         | P37CFG | P36CFG | P35CFG | P34CFG | P33CFG | P32CFG | P31CFG | P30CFG |
| Offset address | 0x3e   | 0x3c   | 0x3a   | 0x38   | 0x36   | 0x34   | 0x32   | 0x30   |

Remark: For specific function mapping, refer to Table 2-2: Digital Mapping of Pin Functions.

www.mcu.com.cn 30 / 624 Rev.1.0.3

## 2.3.11 Description of the special function port RESINB

RESINB is valid by default when the product is powered on, if you need to use this port as GPIO, then you need to turn off the reset function through the registers, and the registers are described as follows.

Base address: 0x40020400 Offset address: 0x0B

| Symbol | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0    | Reset<br>value | R/W |
|--------|---|---|---|---|---|---|---|------|----------------|-----|
| RSTM   | 0 | 0 | 0 | 0 | 0 | 0 | 0 | RSTM | 00H            | R/W |

| RSTM | External reset function mask on RESINB pin |  |  |  |
|------|--|--|--|--|
| 0    | RESINB external reset pin                  |  |  |  |
| 1    | RESINB as GPIO pin                         |  |  |  |

# **Chapter 3 System Architecture**

#### 3.1 Overview

This product system consists of the following components:

- 1 AHB buses Master:
  - Cortex-M0+
- 3 AHB buses Slaves:
  - FLASH memory
  - SRAM memory
  - AHB to APB Bridge, contains all APB interface peripherals

Figure 3-1: Block diagram of system architecture

- 1) System Bus: This bus connects the system bus (peripheral bus) of the Cortex-M0+ core to the bus matrix.
- 2) Bus Matrix: The bus matrix coordinates access to other buses on the core system bus.
- 3) AHB to APB Bridge: The AHB to APB Bridge provides a synchronous connection between the AHB and APB buses. Refer to Figure 3-1 for address mapping of the different peripherals connected to each bridge.

www.mcu.com.cn 32 / 624 Rev.1.0.3

# 3.2 System address partitioning

# **Chapter 4 Clock Generation Circuit**

The presence or absence of the resonator connection pin/external clock input pin for the main system clock and the resonator connection pin/external clock input pin for the sub-system clock varies by product.

#### 4.1 Function of clock generation circuit

The clock generation circuit is a circuit that generates a clock supplied to the CPU and peripheral hardware. There are the following 3 types of system clock and clock oscillation circuits.

- (1) Main system clock
  - ① X1 oscillation circuit
    - The clock of  $F_X=4\sim16MHz$  can be oscillated by connecting resonators to pins X1 and X2, and the oscillation can be stopped by entering deep sleep mode or by setting the MSTOP bit (bit 7 of the clock operation status control register (CSC)).
  - ② High-speed on-chip oscillator (high-speed OCO)

    The frequency at which to oscillate can be selected from among F<sub>IH</sub>=64MHz, 48MHz, 32MHz, 24MHz, 16MHz, 12MHz, 8MHz, 6MHz, 4MHz, 3MHz and 2MHz by using the option byte (000C2H). After the reset is released, the CPU must start operation with this high-speed on-chip oscillator clock F<sub>IH</sub>. Oscillation can be stopped by entering deep sleep mode or by setting the HIOSTOP bit (bit0 of the CSC register). The frequency set by the option byte can be changed by the frequency selection register (HOCODIV) of the high-speed on-chip oscillator. Refer to "Table 4-11: Format of high-speed on-chip oscillator frequency select register (HOCODIV)" for frequency settings.

In addition, an external master system clock (F<sub>EX</sub>=4~16MHz) can be provided by the EXCLK/X2 pin, and the input of the external master system clock can be disabled by entering deep sleep mode or setting the MSTOP bit.

Switching between the high-speed system clock (X1 clock or external master system clock) and the high-speed on-chip oscillator clock can be performed by setting the MCM0 bit (bit 4 of the system clock control register (CKC)).

#### (2) Subsystem clock

XT1 oscillation circuit

The clock of  $F_{XT}$ =32.768KHz can be oscillated by connecting 32.768KHz resonators to the XT1 and XT2 pins, and the oscillation can be stopped by setting the XTSTOP bit (bit 6 of the clock operation status control register (CSC)).

In addition, an external subsystem clock (F<sub>EXS</sub>=32.768KHz) can be provided by the EXCLKS/XT2 pin, and the input of the external subsystem clock can be disabled by setting the XTSTOP bit.

(3) Low-speed on-chip oscillator clock (low-speed OCO)

www.mcu.com.cn 35 / 624 Rev.1.0.3

This circuit oscillates a clock of  $F_{IL} = 15 \text{ KHz}$ .

The low-speed on-chip oscillator clock can be used as the system clock.

The low-speed on-chip oscillator oscillates when bit4 (WDTON) of the option byte (000C0H) or bit4 (WUTMMCK0) of the subsystem clock supply mode control register (OSMC) is "1" or when bit0 (SELLOSC) of the subsystem clock selection register (SUBCKSEL) is "1".

However, the low-speed on-chip oscillator stops oscillating if the deep sleep mode or sleep mode is entered when the WDTON bit is "1" and the WUTMMCK0 bit, the SELLOSC bit is "0" and bit0 (WDSTBYON) of the option byte (000C0H) is "0".

Notice: The low-speed on-chip oscillator clock ( $F_{IL}$ ) can be selected as the count clock for the real-time clock only when the fixed-cycle interrupt function is used.

Remark: F<sub>X</sub>: X1 clock oscillation frequency

 $F_{\mbox{\scriptsize HOCO}}$ : High-speed on-chip oscillator clock frequency

F<sub>IH</sub>: High-speed on-chip oscillator clock frequency

F<sub>EX</sub>: External main system clock frequency

## 4.3 Registers for controlling clock generation circuit

The clock generation circuit is controlled through the following registers.

Clock operation mode control register (CMC)

System clock control register (CKC)

Clock operation status control register (CSC)

Oscillation stabilization time counter status register (OSTC)

Oscillation stabilization time select register (OSTS)

Peripheral enable registers 0, 1 (PER0, PER1)

Subsystem clock supply mode control register (OSMC)

High-speed on-chip oscillator frequency select register (HOCODIV)

High-speed on-chip oscillator trimming register (HIOTRM)

Subsystem clock select register (SUBCKSEL)

Notice: The assigned registers and bits vary from product to product. The initial values must be set for unassigned bits.

#### 4.3.1 Clock operation mode control register (CMC)

This is the register that sets the operation mode of the X1, X2/EXCLK, XT1, and XT2/EXCLKS pins and selects the gain of the oscillation circuit.

The CMC register can be written only once by an 8-bit memory manipulation instruction after the reset is released. Reading this register can be done with an 8-bit memory manipulation instruction.

After a reset signal is generated, the value of this register changes to "00H".

www.mcu.com.cn 40 / 624 Rev.1.0.3

Table 4-2: Format of clock operation mode control register (CMC)

Address: 40020400H After reset: R/W Note 1

00H

| Symbol | 7     | 6      | 5              | 4               | 3 | 2             | 1              | 0 |

|-------|--------|---|---|----------------------|
| 0     | 0      | Port mode Input/output port                   |   |                      |
| 0     | 1      | X1 oscillation mode                           | Connect a crystal or ceramic resonator. |                      |
| 1     | 0      | Port mode                                     | Input/output port                       |                      |
| 1     | 1      | External clock input mode                     | Input/output port                       | External clock input |

| EXCLKS | OSCSELS | Operation mode of subsystem clock pin | XT1 pin XT2/EXCLKS pin       |                      |  |
|--------|---------|---------------------------------------|------------------------------|----------------------|--|
| 0      | 0       | Port mode                             | Input/output port            |                      |  |
| 0      | 1       | XT1 oscillation mode                  | Connect a crystal resonator. |                      |  |
| 1      | 0       | Port mode                             | Input/output port            |                      |  |
| 1      | 1       | External clock input mode             | Input/output port            | External clock input |  |

| AMPHS1 | AMPHS0 | Selection of oscillation modes for XT1 oscillation circuit |  |  |  |
|--------|--------|--|--|--|--|
| 0      | 0      | ow power oscillation (default)                             |  |  |  |
| 0      | 1      | lormal oscillation   |  |  |  |
| 1      | 0      | ow power oscillation                                       |  |  |  |
| 1      | 1      | Disable setting.   |  |  |  |

Note 1: Bit3 is a write-only bit.

- Note 2: The EXCLKS bit, the OSCSELS bit, the AMPHS1 bit and the AMPHS0 bit are initialized only at power-on reset and remain unchanged at other resets.
- Note 3: The CMC register can be written only once by an 8-bit memory manipulation instruction after the reset is released. When the CMC register is used at the initial value ("00H"), the CMC register must be set to "00H" after reset is released in order to prevent misoperation in the event of program runaway (the value other than "00H" cannot be recovered if it is written by mistake).
- Note 4: The CMC register must be set after the reset is released and before starting X1 or XT1 oscillation by setting the clock operation status control register (CSC).
- Note 5: The AMPHS1 bit and AMPHS0 bit must be set after the reset is released and in the state where FIH is selected as the  $F_{CLK}$  (the state before switching the  $F_{CLK}$  to  $F_{MX}$  or  $F_{SUB}$ ).
- Note 6: The oscillation stabilization time of the  $F_{XT}$  must be counted by software.
- Note 7: The maximum frequency of the system clock is 64MHz, but the maximum frequency of the X1 oscillator circuit is 16MHz.

Note 8: F<sub>X</sub>: X1 clock oscillation frequency.

www.mcu.com.cn 41 / 624 Rev.1.0.3

## 4.3.2 System clock control register (CKC)

This is a register that selects the CPU/peripheral hardware clock and the main system clock.

The CKC register is set by an 8-bit memory manipulation instruction.

After the reset signal is generated, the value of this register changes to "00H".

Table 4-3: Format of system clock control register (CKC)

| Addres<br>s: | 40020404H | After reset:<br>00H | R/W Note1 |      |   |   |   |   |
|--------------|-----------|---------------------|-----------|------|---|---|---|---|
| Symbol       | 7         | 6                   | 5         | 4    | 3 | 2 | 1 | 0 |
| CKC          | CLS       | CSS                 | MCS       | MCM0 | 0 | 0 | 0 | 0 |

| MC | S | Status of the main system clock (F <sub>MAIN</sub> )   |  |  |  |
|----|---|--|--|--|--|
| 0  |   | High-speed on-chip oscillator clock (F <sub>IH</sub> ) |  |  |  |
| 1  |   | High-speed system clock (F <sub>MX</sub> )             |  |  |  |

| MCM0 <sup>Note1</sup> | Operation control of the main system clock (FMAIN)  |  |  |  |  |
|-----------------------|---|--|--|--|--|
| 0                     | The high-speed on-chip oscillator clock (F <sub>IH</sub> ) is selected as the main system clock (F <sub>MAIN</sub> ). |  |  |  |  |
| 1                     | The high-speed system clock (F <sub>MX</sub> ) is selected as the main system clock (F <sub>MAIN</sub> ).             |  |  |  |  |

Note 1: Bit7 and bit5 are read-only bits, bit0~3 must be set to "0".

Note: It is prohibited to change the value of the MCM0 bit with the CSS bit set to "1".

#### Remark:

- 1. Provides CSS bit setting clocks for the CPU and peripheral hardware. If you change the CPU clock, change the peripheral hardware clock at the same time (except for real-time clocks, 15-bit interval timers, clock output/buzzer output, and watchdog timer). Therefore, if you want to change the clock on the CPU/peripheral hardware, you must stop the peripheral functions.
- 2. If the subsystem clock is used as the peripheral hardware clock, operation of the A/D converter and IICA cannot be guaranteed. For the operating characteristics of the peripheral hardware, refer to the sections and datasheets for each peripheral hardware.
- 3. F<sub>HOCO</sub>: High-speed on-chip oscillator clock frequency

F<sub>IH</sub>: High-speed on-chip oscillator clock frequency

F<sub>MX</sub>: High-speed system clock frequency

F<sub>MAIN</sub>: Main system clock frequency F<sub>SUB</sub>: Subsystem clock frequency

#### 4.3.3 Clock operation status control register (CSC)

This is the register that controls the operation of the high-speed system clock, the high-speed on-chip oscillator clock, and the subsystem clock (except the low-speed internal oscillator clock). The CSC register is set by an 8-bit memory manipulation instruction.

After a reset signal is generated, the value of this register changes to "C0H".

Table 4-4: Format of the clock operation status control register (CSC)

| Addres<br>s: | 40020401H | After reset:<br>C0H | R/W |   |   |   |   |         |
|--------------|-----------|---------------------|-----|---|---|---|---|---------|
| Symbol       | 7         | 6                   | 5   | 4 | 3 | 2 | 1 | 0       |
| CSC          | MSTOP     | XTSTOP              | 0   | 0 | 0 | 0 | 0 | HIOSTOP |

| MSTOP   | Operation control of high-speed system clock |  |                    |  |  |
|---------|--|--|--------------------|--|--|
| IVISTOP | X1 oscillation mode                          | External clock input mode                      | Port mode          |  |  |
| 0       | X1 oscillation circuit runs                  | The external clock on the EXCLK pin is valid   |                    |  |  |
| 1       | X1 oscillation circuit stops                 | The external clock on the EXCLK pin is invalid | input/output ports |  |  |

| XTSTOP | Operation control of subsystem clock |   |                   |  |  |  |
|--------|--------------------------------------|---|-------------------|--|--|--|
| XISTOP | XT1 oscillation mode                 | External clock input mode                       | Port mode         |  |  |  |
| 0      | XT1 oscillation circuit runs         | The external clock on the EXCLKS pin is valid   |                   |  |  |  |
| 1      | XT1 oscillation circuit stops        | The external clock on the EXCLKS pin is invalid | inpuroutput ports |  |  |  |

| HIOSTOP | Operation control of high-speed on-chip oscillator clock |  |
|---------|--|--|
| 0       | ligh-speed on-chip oscillator runs                       |  |
| 1       | ligh-speed on-chip oscillator stops                      |  |

#### Notice:

- 1. After reset release, set the clock operation mode control register (CMC) before setting the CSC register.
- 2. Set the oscillation stabilization time select register (OSTS) before setting the MSTOP bit to 0 after releasing reset. Note that if the OSTS register is being used with its default settings, the OSTS register is not required to be set here.
- 3. To start X1 oscillation as set by the MSTOP bit, check the oscillation stabilization time of the X1 clock by using the oscillation stabilization time counter status register (OSTC).
- 4. When starting XT1 oscillation by setting the XSTOP bit to 0, wait for oscillation of the subsystem clock to stabilize by setting a wait time using software.
- 5. Do not stop the clock selected for the CPU peripheral hardware clock (FCLK) with the CSC register.

Remark: The setting of the flags of the register to stop clock oscillation (invalidate the external clock input) and the condition before clock oscillation is to be stopped are as Table 4-5.

Table 4-5: Condition before stopping clock oscillation

| Clock                      | Condition before stopping clock (Invalidating external clock input)     | Setting of CSC register flags |
|----------------------------|---|-------------------------------|
|                            | CPU/peripheral hardware clock runs on a clock other than the high-speed |                               |

## 4.3.4 Oscillation stabilization time counter status register (OSTC)

This is the register that indicates the count status of the X1 clock oscillation stabilization time counter. The X1 clock oscillation stabilization time can be checked in the following cases:

If the X1 clock starts oscillation while the high-speed on-chip oscillator clock or subsystem clock is being used as the CPU clock.

If the deep sleep mode is entered and then released while the high-speed on-chip oscillator clock is being used as the CPU clock with the X1 clock oscillating.

The OSTC register can be read by an 8-bit memory manipulation instruction.

The value of this register is changed to "00H" by generating the reset signal, entering the deep sleep mode, or when the MSTOP bit (bit 7 of the clock operation status control register (CSC)) is "1".

Remark: The oscillation stabilization time counter starts counting in the following cases:

- 1) When oscillation of the X1 clock starts (EXCLK, OSCSEL = 0, 1 MSTOP = 0)
- 2) When the deep sleep mode is released

www.mcu.com.cn 45 / 624 Rev.1.0.3

Table 4-6: Format of oscillation stabilization time counter status register (OSTC)

#### Remark:

- 1. After the above time has elapsed, the bits are set to 1 in order from the MOST8 bit and remain 1.
- The oscillation stabilization time counter counts up to the oscillation stabilization time set by the
  oscillation stabilization time select register (OSTS). In the following cases, set the oscillation
  stabilization time of the OSTS register to the value greater than the count value which is to be
  checked by the OSTC register.
  - 1) If the X1 clock starts oscillation while the high-speed on-chip oscillator clock or subsystem clock is being used as the CPU clock.

2)

- 3) If the deep sleep mode is entered and then released while the high-speed on-chip oscillator clock is being used as the CPU clock with the X1 clock oscillating. (Note, therefore, that only the status up to the oscillation stabilization time set by the OSTS register is set to the OSTC register after the deep sleep mode is released.)
- 3. The X1 clock oscillation stabilization wait time does not include the time until clock oscillation starts (see "a" below).

4.  $F_X$ : X1 clock oscillation frequency.

www.mcu.com.cn 46 / 624 Rev.1.0.3

#### 4.3.5 Oscillation stabilization time select register (OSTS)

This register is used to select the X1 clock oscillation stabilization wait time.

If the X1 clock is made to oscillate, it automatically waits for the time set in the OSTS register after the X1 oscillation circuit runs (MSTOP=0).

If the CPU clock is switched from the high-speed on-chip oscillator clock or the sub-system clock to the X1 clock, or if the CPU clock is the high-speed on-chip oscillator clock and is released from deep sleep mode after being transferred to deep sleep mode while the X1 clock is oscillating, it is necessary to confirm whether or not an oscillation stabilization time has elapsed by means of the oscillation stabilization time counter status register (OSTC).

It can confirm the time set in advance by the OSTS register through the OSTC register.

The OSTS register is set by an 8-bit memory manipulation instruction. After a reset signal is generated, the value of this register changes to "07H".

Table 4-7: Format of oscillation stabilization time select register (OSTS)

| Addres<br>s: | 40020403H | After reset:<br>07H | R/W |   |   |       |       |       |

| 0     | 0     | 0     | 2 <sup>8</sup> /F <sub>X</sub>           | 64us                 | 16us     |  |  |
| 0     | 0     | 1     | 2 <sup>9</sup> /F <sub>X</sub>           | 128us                | 32us     |  |  |
| 0     | 1     | 0     | 2 <sup>10</sup> /F <sub>X</sub>          | 256us                | 64us     |  |  |
| 0     | 1     | 1     | 2 <sup>11</sup> /F <sub>X</sub>          | 512us                | 128us    |  |  |
| 1     | 0     | 0     | 2 <sup>13</sup> /F <sub>X</sub>          | 2.048ms              | 512us    |  |  |
| 1     | 0     | 1     | 2 <sup>15</sup> /F <sub>X</sub>          | 8.192ms              | 2.048ms  |  |  |
| 1     | 1     | 0     | 2 <sup>17</sup> /F <sub>X</sub>          | 32.768ms             | 8.192ms  |  |  |
| 1     | 1     | 1     | 2 <sup>18</sup> /Fx                      | 65.536ms             | 16.384ms |  |  |

#### Remark:

- 1. Change the setting of the OSTS register before setting the MSTOP bit of the clock operation status control register (CSC) to 0.
- The oscillation stabilization time counter counts up to the oscillation stabilization time set by the OSTS register. In the following cases, set the oscillation stabilization time of the OSTS register to the value greater than the count value which is to be checked by the OSTC register after the oscillation starts.
  - 1) If the X1 clock starts oscillation while the high-speed on-chip oscillator clock or subsystem clock is being used as the CPU clock.
  - 2) If the deep sleep mode is entered and then released while the high-speed on-chip oscillator clock is being used as the CPU clock with the X1 clock oscillating. (Note, therefore, that only the status up to the oscillation stabilization time set by the OSTS register is set to the OSTC register after the deep sleep mode is released.)
- 3. The X1 clock oscillation stabilization wait time does not include the time until clock oscillation starts (see "a" below).

www.mcu.com.cn 47 / 624 Rev.1.0.3

4. F<sub>X</sub>: X1 clock oscillation frequency.

## 4.3.6 Peripheral enable registers 0, 1 (PER0, PER1)

These registers are used to enable or disable supplying the clock to the peripheral hardware. Clock supply to the hardware that is not used is also stopped so as to decrease the power consumption and noise. When using the following peripheral functions controlled by these registers, the corresponding bit must be set to "1" before initial setting of the peripheral functions.

Real-time clock, 15-bit interval timer

A/D converter

Serial interface IICA0

General-purpose serial communication unit 1

General-purpose serial communication unit 0

General-purpose timer unit 1

General-purpose timer unit 0

**EPWM** 

SPI

The PER0 register and PER1 register are set by an 8-bit memory manipulation instruction.

After a reset signal is generated, the value of these registers changes to "00H".

Table 4-8: Format of peripheral enable register 0 (PER0) (1/3)

## 4.3.7 Subsystem clock supply mode control register (OSMC)

This register is used to reduce power consumption by stopping unnecessary clock functions.

Setting the RTCLPC bit to "1" stops clocking peripheral functions other than the real-time clock and the 15-bit interval timer in the deep sleep mode or in the sleep mode in which the CPU operates with the subsystem clock, and thus reduces power consumption.

In addition, the real-time clock and the operation clock of the 15-bit interval timer can be selected via the OSMC register.

The OSMC registers are set by an 8-bit memory manipulation instruction.

After a reset signal is generated, the value of this register changes to "00H".

Table 4-10: Format of subsystem clock supply mode control register (OSMC)

| Addres s: | 40020423H | After reset:<br>00H | R/W | 117      |   | 5 ( | , |   |

# 4.3.8 High-speed on-chip oscillator frequency select register (HOCODIV)

This is the register that changes the frequency of the high-speed on-chip oscillator set by the option byte (000C2H). However, the frequency that can be selected varies depending on the values of the FRQSEL4 bit and FRQSEL3 bit of the option byte (000C2H).

The HOCODIV register is set by an 8-bit memory manipulation instruction.

After the reset signal is generated, the value of this register changes to the set value of the FRQSEL2 to FRQSEL0 bits of the option byte (000C2H).

Table 4-11: Format of high-speed on-chip oscillator frequency select register (HOCODIV) After reset: Setting value of FRQSEL2~FRQSEL0 bits of option byte (000C2H) R/W Address: 40021C20H Symbol 6 3 2 0 5 **HOCODIV** 0 HOCODIV2 HOCODIV1 HOCODIV0

#### Notice:

- 1. The HOCODIV register must be set in the state where the high-speed on-chip oscillator clock (F<sub>IH</sub>) is selected as the CPU/peripheral hardware clock (F<sub>CLK</sub>).
- 2. After changing the frequency via the HOCODIV register, frequency switching is performed after the following transfer times.
  - 1) Runs for up to 3 clocks at the frequency before the change.
  - 2) Wait for up to 3 CPU/peripheral hardware clocks at the changed frequency

www.mcu.com.cn 54 / 624 Rev.1.0.3

## 4.3.9 High-speed on-chip oscillator trimming register (HIOTRM)

This register is used to adjust the accuracy of the high-speed on-chip oscillator. It can be used for self-measurement and accuracy correction of the high-speed on-chip oscillator frequency using a timer with high-precision external clock input, etc. The HIOTRM register is set by an 8-bit memory manipulation instruction.

Table 4-12: Format of high-speed on-chip oscillator trim register (HIOTRM)

| 0       | 0       | 0       | 1       | 0       | 0       |                               |
|         |         |         | •       |         |         |                               |
| 1       | 1       | 1       | 1       | 1       | 0       | ▼                             |
| 1       | 1       | 1       | 1       | 1       | 1       | maximum speed                 |

Note: If the temperature and  $V_{DD}$  pin voltage change after correcting for accuracy, the frequency changes. Notice:

- 1. In case of temperature and V<sub>DD</sub> pin voltage changes, it is necessary to perform calibration before or at regular intervals to request frequency accuracy.
- 2. The reset value is the adjusted value at the time of shipment.
- 3. Each bit of the HIOTRM register corrects the clock accuracy of the high-speed on-chip oscillator by about 0.05%.

www.mcu.com.cn 55 / 624 Rev.1.0.3

## 4.3.10 Subsystem clock select register (SUBCKSEL)

The SUBCKSEL register is the register that selects the subsystem clock  $F_{SUB}$  and the low-speed on-chip oscillator clock  $F_{IL}$ .

The SUBCKSEL register is set by an 8-bit memory manipulation instruction.

After a reset signal is generated, the value of this register changes to "00H".

Table 4-13: Format of subsystem clock select register (SUBCKSEL)

| Address: | 40020407H | After reset:<br>00H | R/W |   |   |   |   |         |
|----------|-----------|---------------------|-----|---|---|---|---|---------|
| Symbol   | 7         | 6                   | 5   | 4 | 3 | 2 | 1 | 0       |

www.mcu.com.cn 56 / 624 Rev.1.0.3

## 4.3.11 Power mode control protection register (PMUKEY)

The PMUKEY register is a register for controlling the protection of PMUCTL by the power supply mode.

The PMUKEY register is set by a 16-bit memory manipulation instruction.

After a reset signal is generated, the value of this register changes to "0000H".

Table 4-14: Format of power mode control protection register (PMUKEY)

| Address: | 40020408H | After reset: | R/W Note1 |

| Other                           | The PMUCTL write setting is invalid.  |

### 4.3.12 Power mode control register (PMUCTL)

The PMUCTL register is the register that controls the enable power supply control mode.

The PMUCTL register is set by an 8-bit memory manipulation instruction.

After a reset signal is generated, the value of this register changes to "00H" and the write protection is turned on, and the write control is released by PMUKEY.

Table 4-15: Format of power mode control register (PMUCTL)

|--------|--|
| 0      | Partial power-down mode disabled.        |
| 1      | Partial power-down mode enabled.         |

Notice: Release PMUCTL write protection via PMUKEY.

www.mcu.com.cn 57 / 624 Rev.1.0.3

## 4.4 System clock oscillation circuit

#### 4.4.1 X1 oscillation circuit

The X1 oscillator circuit is oscillated by a crystal resonator or ceramic resonator (4~16MHz) connected to pins X1 and X2. An external clock can also be input, where a clock signal must be input to the EXCLK pin.

When using the X1 oscillation circuit, bit 7 and bit 6 (EXCLK, OSCSEL) of the clock operation mode control register (CMC) must be set as follows:

Crystal or ceramic oscillation. EXCLK, OSCSEL=0, 1

External clock input: EXCLK, OSCSEL=1, 1

When the X1 oscillation circuit is not used, it must be set to the port mode (EXCLK, OSCSEL=0, 0). Also, refer to "Table 2-3 Handling of Unused Pins" when not used as an input/output port.

An example of an external circuit for the X1 oscillation circuit is shown in Figure 4-2.

Figure 4-2: Example of an external circuit for X1 oscillation circuit

Notices are shown on the next page.

#### 4.4.2 XT1 oscillation circuit

The XT1 oscillation circuit is oscillated by a crystal resonator (32.768KHz (typical)) connected to the XT1 pin and XT2 pin. When using the XT1 oscillation circuit, bit 4 (OSCSELS) of the clock operation mode control register (CMC) must be set to "1" to enable the external clock to be input as well, in which case the clock signal must be input to the EXCLKS pin.

When using the XT1 oscillation circuit, bit 5 and bit 4 (EXCLKS, OSCSELS) of the clock operation mode control register (CMC) must be set as follows:

Crystal oscillation: EXCLKS, OSCSELS=0, 1
External clock input: EXCLKS, OSCSELS=1, 1

When the XT1 oscillation circuit is not used, it must be set to the port mode (EXCLKS, OSCSELS=0, 0). Also, when not used as an input/output port, refer to "Table 2-3 Handling of Unused Pins". An example of an external circuit for the XT1 oscillation circuit is shown in Figure 4-3.

Figure 4-3: Example of an external circuit for XT1 oscillation circuit

Notice: When using the X1 oscillator circuit and the XT1 oscillator circuit, the dashed portions of Figure 4-2(a) and Figure 4-2(b) must be routed in order to avoid the effects of wiring capacitance, etc., by the following method:

- 1) Keep the wiring length as short as possible.
- 2) Do not cross the wiring with the other signal lines. Do not route the wiring near a signal line through which a high fluctuating current flow.
- 3) Always make the ground point of the oscillator capacitor the same potential as V<sub>SS</sub>. Do not ground the capacitor to a ground pattern through which a high current flow.
- 4) Do not fetch signals from the oscillator.

Figure 4-4 shows examples of incorrect resonator connection.

Figure 4-4: Examples of incorrect resonator connection (1/2)

(a) Too long wiring

(b) Crossed signal line

- (c) The X1 and X2 signal line wires cross.
- (d) A power supply/GND pattern exists under the X1 and X2 wires.

#### Notice:

- 1. In multilayer boards or double-sided boards, power or ground graphics should not be configured below the wiring area (dashed portion of the diagram) for pins X1, X2 and the resonator. The wiring must not create a capacitive component that would affect the oscillation characteristics.
- 2. In the case of using the subsystem clock, please read with XT1 and XT2 instead of X1 and X2 respectively, and insert series resistors on the XT2 side.

www.mcu.com.cn 60 / 624 Rev.1.0.3

Figure 4-4: Examples of incorrect resonator connection (2/2)

- (e) Wiring near high alternating current
- (f) Current flowing through ground line of oscillator (potential at points A, B, and C fluctuates)

(g) Signals are fetched

#### Notice:

- 1. When X2 and XT1 are in parallel, the crosstalk noise of X2 will be superimposed to XT1 and cause misoperation.
- 2. In the case of using the subsystem clock, please read with XT1 and XT2 instead of X1 and X2 respectively, and insert series resistors on the XT2 side.

www.mcu.com.cn 61 / 624 Rev.1.0.3

#### 4.4.3 High-speed on-chip oscillator

The CMS32L032 has a built-in high-speed on-chip oscillator. The frequency can be selected from 64MHz, 48MHz, 32MHz, 24MHz, 16MHz, 12MHz, 8MHz, 6MHz, 4MHz, 3MHz, and 2MHz using the option byte (000C2H). Oscillation can be controlled by bit0 (HIOSTOP) of the clock operation status control register (CSC).

The high-speed on-chip oscillator automatically starts oscillating after power-on reset is released.

## 4.4.4 Low-speed on-chip oscillator

The CMS32L032 has a built-in low-speed on-chip oscillator.

The low-speed on-chip oscillator clock is used as the clock for the watchdog timer, the real-time clock, the 15-bit interval timer, and the external reference clock for the SysTick timer, as well as the CPU clock and peripheral module clock.

When bit4 (WDTON) of the option byte (000C0H) or bit4 (WUTMMCK0) of the subsystem clock supply mode control register (OSMC) is "1", the low-speed on-chip oscillator oscillator.

When the watchdog timer stops running and the WUTMMCK0 bit is not "0", the low-speed internal oscillator continues to oscillate. However, if the watchdog timer is running and the WUTMMCK0 bit or the SELLOSC bit is "0", the low-speed internal oscillator stops oscillating when the WDSTBYON bit is "0" and it is in the sleep mode or deep sleep mode. When the watchdog timer is running, the low-speed internal oscillator clock does not stop running even if the program is out of control.

www.mcu.com.cn 62 / 624 Rev.1.0.3

## 4.5 Operation of clock generation circuit

The clock generation circuit generates various clocks as shown below and controls the CPU operation modes such as standby mode (refer to Figure 4-1).

F<sub>MAIN</sub>: Main system clock frequency

 $F_{MX}$ : High-speed system clock frequency

F<sub>X</sub>: X1 clock oscillation frequency

FEX: External main system clock frequency

FIH: High-speed on-chip oscillator clock frequency

F<sub>SUB</sub>: Subsystem clock frequency F<sub>XT</sub>: XT1 clock oscillation frequency

F<sub>EXS</sub>: External subsystem clock frequency

F<sub>CLK</sub>: CPU/peripheral hardware clock frequency F<sub>IL</sub>: Low-speed on-chip oscillator clock frequency

After the CMS32L032 is released from reset, the CPU begins operation through the output of the high-speed on-chip oscillator. The operation of the clock generation circuit when the power is turned on is shown in Figure 4-5.

Figure 4-5: Operation of the clock generation circuit when the power is turned on

- After power is turned on, an internal reset signal is generated through the power-on reset (POR) circuit. However, the reset state is maintained by a voltage detection circuit or an external reset until the operating voltage range shown in the AC characteristics of the datasheet is reached (the above figure shows an example when an external reset is used).
- 2) The high-speed on-chip oscillator starts oscillating automatically after the reset is released.
- After the reset is released, voltage stabilization waiting and reset processing are performed, and then the CPU starts running with a high-speed on-chip oscillator clock.
- 4) The start of oscillation of the X1 clock or XT1 clock must be set by software (see "4.6.2 Example of setting X1 oscillation circuit" and "4.6.3 Example of controlling XT1 oscillation clock").
- 5) If you want to switch the CPU clock to X1 clock or XT1 clock, you must set the switch by software after waiting for the clock oscillation to stabilize (see"4.6.2 Example of setting X1 oscillation circuit"and "4.6.3 Example of controlling XT1 oscillation clock").

Note 1: When the reset is released, the oscillation stabilization time of the X1 clock must be confirmed by the oscillation stabilization time counter status register (OSTC).

Remark: If you use an external clock input from the EXCLK pin, there is no need for an oscillation stabilization wait time.

www.mcu.com.cn 64 / 624 Rev.1.0.3

#### 4.6 Clock control

## 4.6.1 Example of setting up a high-speed on-chip oscillator

The CPU/peripheral hardware clock ( $F_{CLK}$ ) must run at the high-speed on-chip oscillator clock after the reset is released. The frequency of the high-speed on-chip oscillator can be selected from 64MHz, 48MHz, 32MHz, 24MHz, 16MHz, 12MHz, 8MHz, 6MHz, 4MHz, 3MHz, and 2MHz by using bits FRQSEL0 to FRQSEL4 of the option byte (000C2H). In addition, the frequency can be changed by the high-speed on-chip oscillator register (HOCODIV).

[Option byte setting]

| Address: | 000C2H |   |   |         |         |         |         |         |
|----------|--------|---|---|---------|---------|---------|---------|---------|
| option   | 7      | 6 | 5 | 4       | 3       | 2       | 1       | 0       |

## 4.6.2 Example of setting X1 oscillation circuit

After a reset release, the CPU/peripheral hardware clock ( $F_{CLK}$ ) always starts operating with the high-speed on-chip oscillator clock. To subsequently change the clock to the X1 oscillation clock, set the oscillator and start oscillation by using the oscillation stabilization time select register (OSTS) and clock operation mode control register (CMC) and clock operation status control register (CSC) and wait for oscillation to stabilize by using the oscillation stabilization time counter status register (OSTC). After the oscillation stabilizes, set the X1 oscillation clock to  $F_{CLK}$  by using the system clock control register (CKC).

[Setting of registers] The registers must be set in the order of ① to ⑤.

① Set the OSCSEL bit of the CMC register to "1" to set the frequency division selection of the X1 clock through MOSCDIV to operate the X1 oscillation circuit.

|     | 7      | 6       | 5       | 4        | 3            | 2       | 1       | 0 |
|-----|--------|---------|---------|----------|--------------|---------|---------|---|
| CMC | EXCLK0 | OSCSEL1 | EXCLKS0 | OSCSELS0 | MOSCDIV<br>0 | AMPHS10 | AMPHS00 | 0 |

② Select the oscillation stabilization time of the X1 oscillation circuit when the deep sleep mode is released through the OSTS register.

Example) Setting values when a wait of at least 102us is set based on a 10 MHz resonator.

|      | 7 | 6 | 5 | 4 | 3 | 2      | 1      | 0      |
|------|---|---|---|---|---|--------|--------|--------|
| OSTS | 0 | 0 | 0 | 0 | 0 | OSTS20 | OSTS11 | OSTS00 |

③ Clear the MSTOP bit of the CSC register to "0" so that the X1 oscillator circuit starts oscillating.

|     | 7      | 6       | 5 | 4 | 3 | 2 | 1 | 0        |
|-----|--------|---------|---|---|---|---|---|----------|
| CSC | MSTOP0 | XTSTOP1 | 0 | 0 | 0 | 0 | 0 | HIOSTOP0 |

④ Wait for the oscillation of the X1 oscillation circuit to stabilize through the OSTC register.

Example) Wait until the bits reach the following values when a wait of at least 102us is set based on a 10 MHz resonator.

|      | 7      | 6      | 5       | 4       | 3       | 2       | 1       | 0       |   |
|------|--------|--------|---------|---------|---------|---------|---------|---------|---|
| OSTC | MOST81 | MOST91 | MOST101 | MOST110 | MOST130 | MOST150 | MOST170 | MOST180 | 1 |

⑤ Set the X1 oscillating clock to the CPU/peripheral hardware clock via the MCM0 bit of the CKC register.

|     | 7    | 6    | 5    | 4     | 3 | 2 | 1 | 0 |
|-----|------|------|------|-------|---|---|---|---|
| CKC | CLS0 | CSS0 | MCS0 | MCM01 | 0 | 0 | 0 | 0 |

www.mcu.com.cn 67 / 624 Rev.1.0.3

## 4.6.3 Example of controlling XT1 oscillation clock

After a reset release, the CPU/peripheral hardware clock ( $F_{CLK}$ ) always starts operating with the high-speed on-chip oscillator clock. To subsequently change the clock to the XT1 oscillation clock, set the oscillator and start oscillation by using the operation speed mode control register (OSMC), clock operation mode control register (CMC), and clock operation status control register (CSC), set the XT1 oscillation clock to  $F_{CLK}$  by using the system clock control register (CKC).

[Setting of registers] The registers must be set in the order of ① to ⑤.

① In the deep sleep mode or the sleep mode where the CPU is running on the sub-system clock, the RTCLPC bit must be set to "1" whenever the real-time clock and the 15-bit interval timer are made to run on the sub-system clock (Low consumption current).

|      | 7             | 6 | 5 | 4         | 3 | 2 | 1 | 0 |
|------|---------------|---|---|-----------|---|---|---|---|
| OSMC | RTCLPC<br>0/1 | 0 | 0 | WUTMMCK00 | 0 | 0 | 0 | 0 |

② Set the OSCSELS bit of the CMC register to "1" to operate the XT1 oscillation circuit.

|     | 7      | 6       | 5       | 4        | 3       | 2             | 1             | 0 |
|-----|--------|---------|---------|----------|---------|---------------|---------------|---|
| CMC | EXCLK0 | OSCSEL0 | EXCLKS0 | OSCSELS1 | MOCDIV0 | AMPHS1<br>0/1 | AMPHS0<br>0/1 | 0 |

AMPHS0 bit and AMPHS1 bit: Set the oscillation mode of XT1 oscillation circuit.

③ Clear the XTSTOP bit of the CSC register to "0" so that the XT1 oscillator circuit starts oscillating.

|     | 7      | 6       | 5 | 4 | 3 | 2 | 1 | 0        |
|-----|--------|---------|---|---|---|---|---|----------|
| CSC | MSTOP1 | XTSTOP0 | 0 | 0 | 0 | 0 | 0 | HIOSTOP0 |

- The oscillation stabilization time required by the subsystem clock must be waited for by software, timer function, etc.
- Set the XT1 oscillating clock to the CPU/peripheral hardware clock via the CSS bit of the CKC register.

|     | 7    | 6    | 5    | 4    | 3 | 2 | 1 | 0 |   |
|-----|------|------|------|------|---|---|---|---|---|

#### 4.6.4 CPU clock status transition diagram

Figure 4-6 shows the CPU clock status transition diagram of this product.

Figure 4-6: State transfer diagram for CPU clock

Examples of CPU clock transfer and SFR register setting are in Table 4-16.

Table 4-16: CPU clock transition and SFR register setting examples (1/4)

(1) CPU operating with high-speed on-chip oscillator clock (B) after reset release (A)

| Status transition | SFR register setting  |
|-------------------|---|
| (A)→(B)           | SFR registers do not have to be set (default status after reset release). |

(2) CPU operating with high-speed system clock (C) after reset release (A) (The CPU operates (B) with a high-speed on-chip oscillator clock immediately after the reset is released)

(SFR register setting order)

| SFR register setting flag                           | CMC register Note 1 |        | OSTS<br>register | CSC<br>register | OSTC<br>register   | CKC<br>register |
|---|---------------------|--------|------------------|-----------------|--------------------|-----------------|
| State transition                                    | EXCLK               | OSCSEL | register         | MSTOP           | register           | MCM0            |
| $(A) \rightarrow (B) \rightarrow (C)$<br>(X1 clock) | 0                   | 1      | Note2            | 0               | Need to confirm    | 1               |
| (A)→(B)→(C)<br>(External main system clock)         | 1                   | 1      | Note2            | 0               | No need to confirm | 1               |

(3) After the reset (A) is released, the CPU is transferred to the subsystem clock to operate (D). (The CPU operates (B) with a high-speed on-chip oscillator clock immediately after the reset is released)

(SFR register setting order)

| ( or it regions coming or ac                         | .,     |         |                         |        |                 |                           |                 |
|--|--------|---------|-------------------------|--------|-----------------|---------------------------|-----------------|
| SFR register setting flag                            |        | CMC reg | ister <sup>Note 3</sup> |        | CSC<br>register | Oscillation stabilization | CKC<br>register |

| $(A) \rightarrow (B) \rightarrow (D)$<br>(XT1 clock) | 0      | 1       | 0/1                     | 0/1    | 0               | Need                      | 1               |
| (A)→(B)→(D)<br>(External subsystem clock)            | 1      | 1       | ×                       | ×      | 0               | Need                      | 1               |

Note 1: The clock operation mode control register (CMC) can only be written 1 time by an 8-bit memory manipulation instruction after the reset is released.

Note 2: The oscillation stabilization time of the oscillation stabilization time selection register (OSTS) must be set as follows.

Expected oscillation stabilization time of oscillation stabilization time counter status register (OSTC) ≤ oscillation stabilization time set in the OSTS register

Note 3: The clock operation mode control register (CMC) can only be written 1 time by an 8-bit memory manipulation instruction after the reset is released.

Notice: The clock must be set after the supply voltage reaches the set clock runnable voltage (refer to the datasheet for electrical characteristics).

#### Remark:

## 4.6.6 Time required to switch CPU clock and main system clock

It can switch CPU clock (main system clock system clock) and main system clock (high speed internal oscillator clock system clock) by setting bit6 and bit4 (CSS, MCM0) of system clock control register.

The actual switchover does not occur immediately after the CKC register is overridden, but several clocks continue to run with the clock before the switchover after the CKC register is changed (see Table 4-18~Table 4-20).

The CPU can be judged by the bit7 (CLS) of the CKC register whether the CPU is run with the main system clock or the sub system clock. The bit5 (MCS) of the CKC register can be used to determine whether the main system clock operates with a high-speed system clock or a high-speed on-chipl oscillator clock.

If you switch the CPU clock, switch the peripheral hardware clock at the same time.

Table 4-18: Maximum time required to switch main system clock

| Clock A           | Switch direction | Clock B          | Remark               |
|-------------------|------------------|------------------|----------------------|
| Filh              | <b>←→</b>        | F <sub>MX</sub>  | Refer to Table 4-18. |
| F <sub>MAIN</sub> | <b>←→</b>        | F <sub>SUB</sub> | Refer to Table 4-19. |

Table 4-19: Maximum number of clocks required for F<sub>IH</sub>↔F<sub>MX</sub>

| Set value before switching            |                                   | Set value a                               | after switching                           |
|---------------------------------------|-----------------------------------|---|---|
| МСМ0                                  |                                   | N   | ICM0                                      |
|                                       |                                   | 0   | 1   |
|                                       |                                   | (FMAIN=FIH)                               | (FMAIN=FMX)                               |
| 0                                     | F <sub>MX</sub> ≥F <sub>IH</sub>  |   | 2 clocks                                  |
| (F <sub>MAIN</sub> =F <sub>IH</sub> ) | F <sub>MX</sub> <f<sub>IH</f<sub> |   | 2 F <sub>IH</sub> /F <sub>MX</sub> clocks |
| 1                                     | F <sub>MX</sub> ≥F <sub>IH</sub>  | 2 F <sub>MX</sub> /F <sub>IH</sub> clocks |   |
| (FMAIN=FMX)                           | F <sub>MX</sub> <f<sub>IH</f<sub> | 2 clocks                                  |   |

Table 4-20: Maximum number of clocks required for F<sub>MAIN</sub>↔F<sub>SUB</sub>

| Set value before switching | Set value after switching |  |
|----------------------------|---------------------------|--|
|                            |                           | CSS  |
| CSS                        | 0                         | 1  |
|                            | (Fclk=Fmain)              | (Fclk=Fsub)                                    |
| 0<br>(Fclk=Fmain)          |                           | 1+2 F <sub>MAIN</sub> /F <sub>SUB</sub> clocks |
| 1<br>(Fclk=Fsub)           | 3 clocks                  |  |

#### Remark:

- 1. The number of clocks in Table 4-19 and Table 4-20 is the number of CPU clocks before the switch.
- 2. The number of clocks in Table 4-19 and Table 4-20 is the number of clocks rounded to the decimal portion.

Example when switching the main system clock from the high-speed system clock to the high-speed on-chip oscillator clock (oscillation with  $F_{IH}$ =8MHz,  $F_{MX}$ =10MHz)  $2F_{MX}/F_{IH}$ =2(10/8)=2.53 clocks

www.mcu.com.cn 77 / 624 Rev.1.0.3

## 4.6.7 Conditions before clock oscillation is stopped

The following lists the register flag settings for stopping the clock oscillation (disabling external clock input) and conditions before the clock oscillation is stopped.

Table 4-21: Conditions and flag settings before clock oscillation stops

|                                     | Conditions before clock oscillation is stopped (external clock input disabled)          |           |
|-------------------------------------|---|-----------|
| High-speed on-chip oscillator clock | MCS=1 or CLS=1 (CPU runs at a clock other than the high-speed on-chip oscillator clock) | HIOSTOP=1 |
| X1 clock External main system clock | (MCS=0 or CLS=1)<br>(CPU runs at a clock other than the high-speed system clock)        | MSTOP=1   |
| XT1 clock                           | CLS=0 (CPU runs at a clock other than the subsystem clock)                              | XTSTOP=1  |

## 4.7 High-speed on-chip oscillation correction

### 4.7.1 High-speed on-chip oscillation self-adjustment function

This function measures the frequency of a high-speed on-chip oscillator using the subsystem clock  $F_{SUB}$  (32.768KHz) as a reference, and corrects the frequency accuracy of the high-speed on-chip oscillator  $F_{HOCO}$  in real time.

Table 4-22 is the operating specifications for the high-speed on-chip oscillation frequency correction function, Figure 4-7 is the block diagram of the high-speed on-chip oscillation frequency correction function.

Table 4-22: Operating specifications for the high-speed on-chip oscillation frequency correction function

| Item                               | Content   |
|------------------------------------|---|
| Reference clock                    | • F <sub>SUB</sub> /2 <sup>9</sup> (subsystem clock 32.768KHz)  |

Note: Calibration time: It varies depending on the number of calibrations.

Calibration period: The total time of frequency measuring stage and frequency calibration stage.

Calibration times: The number of times the frequency is corrected to the expected value range

Figure 4-7: Operating specifications for the high-speed on-chip oscillation frequency correction function

www.mcu.com.cn 79 / 624 Rev.1.0.3

### 4.7.2 Description of register

Table 4-23 shows a list of registers used for the high-speed on-chip oscillation frequency correction function.

Table 4-23: Register list of high-speed on-chip oscillation frequency correction function

| Item             | Structure   |
|------------------|---|
| Control register | High-speed on-chip oscillation frequency correction control register (HOCOFC) |

# 4.7.2.1 High-speed on-chip oscillation frequency correction control register (HOCOFC)

Control register for the high-speed on-chip oscillation frequency correction function.

The HOCOFC register is set by an 8-bit memory manipulation instruction.

After a reset signal is generated, the value of this register becomes "00H".

Table 4-24: Format of high-speed on-chip oscillation frequency correction control register (HOCOFC)

Address: 0x40022400 After reset: 00H R/W Symbol 6 5 7 3 2 0 **HOCOFC FCMD FCIE** 0 0 0 0 0 **FCST** 

| FCMD <sup>Note1</sup> | High-speed on-chip oscillator clock frequency correction function operating mode |
|-----------------------|--|
| 0                     | Continuous operating mode  |
| 1                     | Intermittent operating mode  |

| FCIE | Control of high-speed on-chip oscillator clock frequency correction end interrupt                    |
|------|--|
| 0    | No interrupt is generated when high-speed on-chip oscillator clock frequency correction is completed |
| 1    | An interrupt is generated when high-speed on-chip oscillator clock frequency correction is completed |

| FCSTNote2  | High-speed on-chip oscillator clock frequency correction circuit operation control/status   |  |  |  |  |  |  |
|--|---|--|--|--|--|--|--|
| 0  | High-speed on-chip oscillation frequency correction circuit operation stop/in stop progress |  |  |  |  |  |  |
| 1  | High-speed on-chip oscillation frequency correction circuit operation start/in operation    |  |  |  |  |  |  |
| In continuous action mode, the software writes 0 to stop the action.  In interval action mode, the hardware clears the FCST bit when the correction is complete. |   |  |  |  |  |  |  |

Note 1: When the FCST bit is 1, rewriting the FCMD bit is disabled.

Note 2: When writing 1 to the FCST bit, first confirm that the current value of the FCST bit is 0 before writing 1. Due to the hardware clear priority, when writing 1 to the FCST bit immediately after the interval action is completed (when the high-speed on-chip oscillator frequency correction completion interrupt is generated), the operation should be performed after at least 1 cycle of F<sub>HOCO</sub> after the high-speed on-chip oscillator frequency correction completion interrupt is generated.

#### Notice:

- After writing 0 to the FCST bit (high-speed on-chip oscillator frequency correction circuit stops), F<sub>HOCO</sub> prohibits writing 1 to the FCST bit (high-speed on-chip oscillator frequency correction circuit starts) for 2 cycles.
- 2. Bit5~1 must write 0.

www.mcu.com.cn 80 / 624 Rev.1.0.3

### 4.7.3 Description of operation

#### 4.7.3.1 Overview

The high-speed on-chip oscillator frequency correction function generates a correction cycle based on the subsystem clock (F<sub>SUB</sub>), measures the frequency of the high-speed on-chip oscillator, and corrects the frequency accuracy of the high-speed on-chip oscillator in real time. The clock adjustment repeats the operation of the frequency measurement stage and the frequency correction stage. The correction algorithm is performed in the frequency measurement stage, and the correction value reflecting the result of the correction algorithm is saved in the frequency correction stage.

Table 4-25 is the high-speed on-chip oscillator input frequency and calibration cycle. Figure 4-8 is the action block diagram of the high-speed on-chip oscillation frequency correction function.

Table 4-25: High-speed on-chip oscillator input frequency and calibration cycle

| FHOCO (MHz) | FRQSEL4-FRQSEL3 <sup>Note</sup> | Correction cycle (ms)                    |
|-------------|---------------------------------|--|
| 64          | 11                              | 31.2                                     |
| 48          | 10                              | (Frequency measurement stage + frequency |
|             |                                 | calibration stage)                       |

In the frequency measurement phase of the calibration cycle, the frequency of the high-speed on-chip oscillator is calibrated using high-speed on-chip oscillator counting based on the result of the magnitude of the counted value and the expected value.

Figure 4-8: Timing diagram of high-speed on-chip oscillation frequency correction (detailed)

Note: FRQSEL4-FRQSEL3 are bit4-bit3 of option byte 00C2H.

Notice: The basic actions of continuous action mode and interval action mode are the same. The difference is whether the clearing of FCST bit is controlled by software or hardware. In addition, only the system reset can clear the correction value.

www.mcu.com.cn 81 / 624 Rev.1.0.3

#### (1) Continuous operating mode

In continuous operating mode, the high-speed on-chip oscillator clock frequency is corrected continuously. This mode is selected by setting the FCMD bit in the HOCOFC register to 0.

Operation of high-speed on-chip oscillator clock frequency correction is started by setting the FCST bit in the HOCOFC register to 1. Similarly, operation of high-speed on-chip oscillator clock frequency correction is stopped by setting the FCST bit in the HOCOFC register to 0.

When operation of high-speed on-chip oscillator clock frequency correction is started, frequency counting starts at the rising edge of the reference clock ( $F_{SUB}/2^9$ ) and stops at the next rising edge of the reference clock ( $F_{SUB}/2^9$ ) in the frequency measurement phase.

Next, the count value and the expected value are compared, and the correction value is adjusted as follows in the frequency correction phase:

When the count value is greater than the expected value: Correction value - 1

When the count value is smaller than the expected value: Correction value + 1

When the count value is in the range of the expected value: The correction value is retained (high-speed on-chip oscillator clock frequency correction is completed)

When the FCIE bit in the HOCOFC register is set to 1, a high-speed on-chip oscillator clock frequency correction end interrupt is output every time high-speed on-chip oscillator clock frequency correction is completed. In continuous operating mode, the frequency measurement phase and the frequency correction phase are repeated until the highspeed on-chip oscillator clock frequency correction function is stopped.

Figure 4-9 shows the continuous operating mode timing.

Figure 4-9: Continuous operating mode timing

www.mcu.com.cn 82 / 624 Rev.1.0.3

#### (2) Intermittent operating mode

In intermittent operating mode, the high-speed on-chip oscillator clock frequency is corrected intermittently using a timer interrupt, etc. This mode is selected by setting the FCMD bit in the HOCOFC register to 1.

Operation of high-speed on-chip oscillator clock frequency correction is started by setting the FCST bit in the HOCOFC register to 1.

When operation of high-speed on-chip oscillator clock frequency correction is started, frequency counting starts at the rising edge of the reference clock ( $F_{SUB}/2^9$ ) and stops at the next rising edge of the reference clock ( $F_{SUB}/2^9$ ) in the frequency measurement phase.

Next, the count value and the expected value are compared, and the correction value is adjusted as follows in the frequency correction phase:

When the count value is greater than the expected value: Correction value - 1

When the count value is smaller than the expected value: Correction value + 1

When the count value is in the range of the expected value: The correction value is retained (high-speed on-chip oscillator clock frequency correction is completed)

While the FCIE bit in the HOCOFC register is set to 1, a high-speed on-chip oscillator clock frequency correction end interrupt is output when high-speed on-chip oscillator clock frequency correction is completed. In intermittent operating mode, the frequency measurement phase and the frequency correction phase are repeated, and highspeed on-chip oscillator clock frequency correction operation is stopped after high-speed on-chip oscillator clock frequency correction is completed.

Figure 4-10 shows the intermittent operating mode timing.

### 4.7.3.2 Operation procedure

The following shows the flow for starting and stopping operation when the high-speed on-chip oscillator clock frequency correction function is used.

<Continuous Operating Mode> <Intermittent Operating Mode> Flow for starting operation Flow for starting operation (1) High-speed on-chip oscillator clock frequency correction Intermittent Operating Mode setting High-speed on-chip oscillator clock frequency correction Continuous Operating Mode setting High-speed on-chip oscillator clock frequency correction CRCTL=C0H CRCTL=40H High-speed on-chip oscillator clock frequency correction end interrupt enabled end interrupt enabled High-speed on-chip oscillator clock frequency correction CRCTL=C1H CRCTL=41H High-speed on-chip oscillator clock frequency correction operation enabled High-speed on-chir oscillator clock No No frequency correction interrupt general frequency correction end interrupt generated? Yes Yes High-speed on-chip oscillator clock frequency correction High-speed on-chip oscillator clock CRCTL=01H frequency correction completed end interrupt disabled Execute processingNote Flow for starting operation (2) Timer interrupt, etc Flow for stopping operation High-speed on-chip oscillator clock frequency correction High-speed on-chip oscillator clock frequency correction CRCTL=00H CRCTL=C1H operation enabled operation stopped High-speed on-chip escillator clock frequency correction end interrupt generated? Yes High-speed on-chip oscillator clock frequency correction completed

Figure 4-11: Example of procedure for setting operating mode

Note: The high-speed on-chip oscillator clock frequency correction is repeated until the high-speed on-chip oscillator clock frequency correction function is stopped.

### 4.7.4 Usage notes

#### 4.7.4.1 SFR access

When writing 1 to FCST to control the FCST bit in intermittent operating mode, confirm that the FCST bit is 0 before writing 1 to the FCST bit. However, when writing 1 to the FCST bit immediately after intermittent operation is completed, wait for at least one F<sub>HOCO</sub> cycle after a high-speed on-chip oscillator clock frequency correction end interrupt is generated.

### 4.7.4.2 Operation during reset

The high-speed on-chip oscillator clock frequency correction function must be stopped before entering deep sleep.

www.mcu.com.cn 85 / 624 Rev.1.0.3

## **Chapter 5 General-Purpose Timer Unit Timer4**

This product is equipped with two general-purpose timer units, each containing four channels. Description:

- 1. The symbol "m" in the following part of this chapter stands for the unit number. This product is equipped with two general-purpose timers, Timer4, so m=0, 1.
  - 2. The symbol "n" in the following part of this chapter stands for the channel number (n=0~3 in this chapter).

Each general-purpose timer unit has four 16-bit timers.

Each 16-bit timer is referred to as a "channel" and can be used individually as a stand-alone timer or in combination with multiple channels for advanced timer functions.

For details of each function, please refer to the following table.

| Tor details or each function, please feler to the following   | owing table.                                 |
|---|--|
| Independent channel operation functions   | Multi-channel linkage operation functions    |
| <ul> <li>Interval timer (refer to 5.8.1)</li> </ul>   | Single trigger pulse output (refer to 5.9.1) |
| <ul> <li>Square wave output (refer to 5.8.1)</li> </ul>   | PWM output (refer to 5.9.2)                  |
| <ul> <li>External event counter (refer to 5.8.2)</li> </ul>   | Multiple PWM outputs (refer to 5.9.3)        |
| <ul> <li>Frequency divider (refer to 5.8.3)</li> </ul>  |  |
| <ul> <li>Measurement of input pulse interval (refer to 5.8.4)</li> </ul>                              |  |
| <ul> <li>Measurement of the high-/low-level width of the input signal<br/>(refer to 5.8.5)</li> </ul> |  |
| <ul> <li>Delay counter (refer to 5.8.6)</li> </ul>  |  |

It is possible to use the 16-bit timer of channels 1 and 3 as two 8-bit timers (higher and lower). The functions that can use channels 1 and 3 as 8-bit timers are as follows:

Interval timer (upper or lower 8-bit timer)/square wave output (lower 8-bit timer only)

External event counter (lower 8-bit timer only)

Delay counter (lower 8-bit timer only)

## 5.1 Function of general-purpose timer unit

The general-purpose timer unit has the following functions.

## 5.1.1 Independent channel operation function

The independent channel operation function is a function that enables independent use of any channel without being affected by other channel operation modes.

#### (1) Interval timer

Each timer of a unit can be used as a reference timer that generates an interrupt (INTTMmn) at fixed intervals.

#### (2) Square wave output

A toggle operation is performed each time INTTMmn interrupt is generated and a square wave with a duty cycle of 50% is output from a timer output pin (TOmn).

#### (3) External event counter

The valid edge of the input signal of the timer input pin (Tlmn) is counted, and if the specified number of times is reached, it can be used as an event counter for generating interrupts.

#### (4) Frequency divider function (channel 0 of unit 0 only)

The input clock from the timer input pin (TI00) is divided and then output from the output pin (TO00).

#### (5) Measurement of input pulse interval

The interval between input pulses is measured by starting counting at the active edge of the input pulse signal at the timer input pin (Tlmn) and capturing the count value at the active edge of the next pulse.

www.mcu.com.cn 87 / 624 Rev.1.0.3

(6) Measurement of the high-/low-level width of the input signal

The high- and low-level width of the input signal is measured by starting the count on one edge of the input signal at the timer input pin (Tlmn) and capturing the count value on the other edge.

(7) Delay counter

Counting begins on the active edge of the input signal to the timer input pin (TImn) and an interrupt is generated after an arbitrary delay period.

#### Remark:

- 1. m: unit number (m=0, 1) n: channel number (n=0~3)
- 2. Please refer to "Chapter 2 Port Function" for the configurable timer input/output pins of channel 0~3.

www.mcu.com.cn 88 / 624 Rev.1.0.3

## 5.1.2 Multi-channel linkage operation functions

The multi-channel linked operation function is a combination of a master channel (the reference timer for the master control cycle) and a slave channel (a timer that operates in compliance with the master channel).

The multi-channel linkage operation function can be used as the following modes.

#### (1) Single trigger pulse output

Using the 2 channels in pairs, a single trigger pulse with arbitrary output timing and pulse width can be generated.

#### (2) PWM (Pulse Width Modulation) output

Using the 2 channels in pairs, pulses with arbitrary period and duty cycle can be generated.

#### (3) Multiple PWM (Pulse Width Modulation) outputs

The PWM function can be extended to generate up to 3 PWM signals of any duty cycle with a fixed period using one master channel and multiple slave channels.

www.mcu.com.cn 89 / 624 Rev.1.0.3

#### Remark:

- 1. Note: Please refer to "5.4.1 Basic rules of multi-channel linkage operation function" for the rule details of multi-channel linkage operation function.
- 2. 2. m: unit number (m=0,1) n: channel number (n=0 ~ 3) p, q: slave channel number (n \leq 3)

www.mcu.com.cn 90 / 624 Rev.1.0.3

## 5.1.3 8-bit timer operation function (channels 1 and 3 of unit 0 only)

The 8-bit timer operation function makes it possible to use a 16-bit timer channel in a configuration consisting of two 8-bit timer channels. This function can only be used for channels 1 and 3.

#### Remark:

- 1. There are several rules for using 8-bit timer operation function.
- 2. For details, see 5.4.2 Basic rules of 8-bit timer operation function (channels 1 and 3 only).

## 5.1.4 LIN-bus supporting function (channel 3 of unit 0 only)

The received signal in the LIN-bus communication is checked by the general-purpose timer unit to see if it fits the LIN-bus communication table.

- (1) Detection of wake-up signals
  - The low-level width is measured by starting a count on the falling edge of the input signal at the UARTO serial data input pin (RxD0) and capturing the count value on the rising edge. If the low-level width is greater than or equal to a fixed value, it is considered a wake-up signal.
- (2) Detection of break field
  - After a wake-up signal is detected, the low-level width is measured by counting on the falling edge of the input signal at the UART0 serial data input pin (RxD0) and capturing the count value on the rising edge. If the low-level width is greater than or equal to a fixed value, it is considered a break field.
- (3) Measurement of sync field pulse width

  After the sync field is detected, the low-level width and high-level width of the input signal at the UART0 serial data input pin (RxD0) are measured. Based on the bit space of the sync field measured in this way, the baud rate is calculated.

Remark: Refer to "5.3.13: Input switching control register (ISC)" and "5.8.5: Operation as input signal high and low levelwidth measurement" for the operation setting of LIN-bus support functions.

www.mcu.com.cn 91 / 624 Rev.1.0.3

## 5.2 Structure of general-purpose timer unit

The general-purpose timer unit consists of the following hardware.

Table 5-1: Structure of general-purpose timer unit

| Item              | Structure   |
|-------------------|---|
| Counter           | Timer count register mn (TCRmn)   |
| Register          | Timer data register mn (TDRmn)  |
| Timer input       | TI00~TI03 <sup>Note 1</sup> , TI10~TI13 <sup>Note 1</sup>   |
| Timer output      | TO00~TO03 Note 1, TO10~TO13 Note 1, output control circuit  |
| Control registers | <registers of="" section="" setting="" unit=""> • Peripheral enable register 0 (PER0) • Timer clock select register m (TPSm) • Timer channel enable status register m (TEm) • Timer channel start register m (TSm) • Timer channel stop register m (TTm) • Timer channel stop register o (TIOS0) Note 2 • Timer output enable register m (TOEm) • Timer output register m (TOEm) • Timer output level register m (TOLm) • Timer output mode register m (TOMm)</registers> |

Note 1: The input/output pins of general-purpose timer unit 0 are multiplexed to fixed ports, and the timer input/output pins of channels 0 to 3 of general-purpose timer unit 1 can be configured to each port except RESETB. For details, refer to "Chapter 2 Port Function".

Note 2: Only for channel selection of unit 0.

Note 3: Timer input/output pin configuration for channel 0~3. For details, please refer to "Chapter 2 Port Function".

Remark: m: unit number (m=0, 1) n: channel number (n=0~3)

www.mcu.com.cn 92 / 624 Rev.1.0.3

The block diagram of the general-purpose timer unit is shown in Figure 5-1.

Figure 5-1: Overall block diagram of general-purpose timer unit 0

Remark: F<sub>SUB</sub>: Subsystem clock frequency

F<sub>IL</sub>: Low-speed on-chip oscillator clock frequency

www.mcu.com.cn 96 / 624 Rev.1.0.3

## 5.2.3 Timer count register mn (TCRmn)

The TCRmn register is a 16-bit read-only register that counts the count clock. The count is incremented or decremented synchronously with the rising edge of the count clock.

The operation mode is selected by the MDmn3 to MDmn0 bits of the Timer Mode Register mn (TMRmn) to switch between incremental and decremental counting (refer to "5.3.3: Timer Mode Register mn (TMRmn)").

Table 5-2: Table of timer count register mn (TCRmn)

|       | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|-------|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| TCRmn |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

The count value can be read by reading the timer count register mn (TCRmn).

In the following cases, the count value becomes "FFFFH".

- (1) When a reset signal is generated
- (2) When clearing the TM4mEN bit of the peripheral enable register 0 (PER0)
- (3) At the end of the count of the slave channel in PWM output mode
- (4) At the end of the count of the slave channel in delayed count mode
- (5) At the end of counting of master/slave channels in single trigger pulse output mode
- (6) At the end of the count of the slave channel in the multiple PWM output mode

In the following cases, the count value becomes "0000H".

- (1) When input starts triggering in capture mode
- (2) At the end of the capture in capture mode

#### Remark:

- 1. Even if the TCRmn register is read, the count value is not captured to the timer data register mn (TDRmn).
- 2. 2. m: unit number (m=0, 1) n: channel number (n=0~3)

As shown below, the read values of the TCRmn register vary depending on the operating mode and operating state.

Table 5-3: The read value of the Timer Count Register mn (TCRmn) in various operating modes

| Operation mode                 |                 | Timer Count Register mn (TCRmn) read value <sup>Note1</sup>   |                                       |  |  |  |  |  |  |  |  |
|--------------------------------|-----------------|---|---------------------------------------|--|--|--|--|--|--|--|--|
|                                | Counting method | Value if the operation mode was changed after releasing reset | Counting pause<br>Value at (TTmn = 1) | Counting pause<br>(TTmn=1) after<br>changing the value<br>of the operating<br>mode | Wait after a single<br>count<br>The value at the<br>start of the trigger |  |  |  |  |  |  |
| Interval timer mode            | Count down      | FFFFH   | value when stopped                    | undefined  | -  |  |  |  |  |  |  |
| Capture Mode                   | Count up        | 0000H   | value when stopped                    | undefined  | -  |  |  |  |  |  |  |
| Event counter mode             | Count down      | FFFFH   | value when stopped                    | undefined  | -  |  |  |  |  |  |  |
| Single count mode              | Count down      | FFFFH   | value when stopped                    | undefined  | FFFFH  |  |  |  |  |  |  |
| Capture & Single<br>Count Mode | Count up        | 0000H   | value when stopped                    | undefined  | TDRmn register capture value +1  |  |  |  |  |  |  |

Note 1: It indicates the read value of the TCRmn register when channel n is in the timer stop state (TEmn=0) and the count enable state (Tsmn=1). Hold this value in the TCRmn register until counting starts.

Remark: m: unit number (m=0, 1) n: channel number (n=0~3)

## 5.2.4 Timer data register mn (TDRmn)

This is a 16-bit register from which a capture function and a compare function can be selected. The capture or compare function can be switched by selecting an operation mode by using the MDmn3 to MDmn0 bits of timer mode register mn (TMRmn).

The value of the TDRmn register can be changed at any time.

This register can be read or written in 16-bit units.

In addition, for the TDRm1 and TDRm3 registers, while in the 8-bit timer mode (when the SPLIT bits of timer mode registers m1 and m3 (TMRm1, TMRm3) are 1), it is possible to rewrite the data in 8-bit units, with TDRm1H and TDRm3H used as the higher 8 bits, and TDRm1L and TDRm3L used as the lower 8 bits.

Reset signal generation clears this register to 0000H.

| Table 5-4: Table of timer data registers mn (TDRmn) (n=0, 2) |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|--|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
|  | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| TDRmn  |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

Table 5-5: Table of timer data registers mn (TDRmn) (n=1, 3) (TDR01H supports 8-bit operation) (TDR01L supports 8-bit operation)

|       | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|-------|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| TDRmn |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

- (1) When timer data register mn (TDRmn) is used as compare register
  - Counting down is started from the value set to the TDRmn register. When the count value reaches 0000H, an interrupt signal (INTTMmn) is generated. The TDRmn register holds its value until it is rewritten.
- (2) When timer data register mn (TDRmn) is used as capture register

The count value of timer count register mn (TCRmn) is captured to the TDRmn register when the capture trigger is input.

A valid edge of the Tlmn pin can be selected as the capture trigger. This selection is made by timer mode register mn (TMRmn).

#### Remark:

- 1. Even if a capture trigger signal is input, the TDRmn register set to the compare function does not perform capture operation.
- 2. m: unit number (m=0, 1) n: channel number (n=0 $\sim$ 3)

www.mcu.com.cn 98 / 624 Rev.1.0.3

## 5.3 Registers for controlling general-purpose timer unit

The registers that control the general-purpose timer unit are as follows:

Peripheral enable register 0(PER0)

Timer clock select register m (TPSm)

Timer mode register mn (TMRmn)

Timer status register mn (TSRmn)

Timer channel enable status register m (TEm)

Timer channel start register m (TSm)

Timer channel stop register m (TTm)

Timer input output selection register (TIOS0)

Timer output enable register m (TOEm)

Timer output register m (TOm)

Timer output level register m (TOLm)

Timer output mode register m (TOMm)

Noise filter enable register 1 (NFEN1)

Noise filter enable register 2 (NFEN2)

Port mode control register (PMCxx)

Port mode register (PMxx)

Port multiplexing function configuration register (PxxCFG)

Notice: The assigned registers and bits vary from product to product. The initial values must be set for unassigned bits.

Remark: Unit number (m=0, 1) n: channel number (n=0~3)

## 5.3.1 Peripheral enable register 0 (PER0)

The PER0 register is the register that sets whether to enable or disable the supply of clocks to each peripheral hardware. Reduce power consumption and noise by stopping clocks to hardware that is not in use.

To use general-purpose timer unit 0, bit0 (TM40EN) must be set to "1". The PER0 register is set by an 8-bit memory manipulation instruction. After a reset signal is generated, the value of the PER0 register changes to "00H".

Table 5-6: Table of peripheral enable register 0 (PER0)

| Address: 0x4002 | 20420 After | reset: 00H | R/W   |         |        |        |        |        |
|-----------------|-------------|------------|-------|---------|--------|--------|--------|--------|
| Symbol          | 7           | 6          | 5     | 4       | 3      | 2      | 1      | 0      |
| PER0            | RTCEN       | 0          | ADCEN | IICA0EN | SAU1EN | SAU0EN | TM41EN | TM40EN |

| TM40EN | Control of the input clock of general-purpose timer unit 0  |
|--------|---|
| 0      | Stop to supply the input clock.  • The SFR used by general-purpose timer unit 0 cannot be written.  • General-purpose timer unit 0 is in the reset state. |
| 1      | Supply the input clock. • The SFR used by general-purpose timer unit 0 can read and write.  |

| TM41EN | Control of the input clock of general-purpose timer unit 1  |
|--------|---|
| 0      | Stop to supply the input clock.  • The SFR used by general-purpose timer unit 1 cannot be written.  • General-purpose timer unit 1 is in the reset state. |
| 1      | Supply the input clock.  • The SFR used by general-purpose timer unit 1 can read and write.   |

Notice: To set the general-purpose timer unit, the following registers must be set with the TM4mEN bit at "1". When the TM4mEN bit is "0", the values of the Timer Array Unit's control registers are initialized, and write operations are ignored (timer input/output select register 0 (TIOS0), noise filter enable register 1 (NFEN1), noise filter enable register 2 (NFEN2), port mode control register (PMCx), port mode register (PMx), and port multiplexing function configuration register (PxxCFG) are excluded).

### 5.3.2 Timer clock select register m (TPSm)

The TPSm register is a 16-bit register that selects the two or four common operating clocks (CKm0, CKm1, CKm2, CKm3) provided to each channel. CKm0 is selected via bits 3~0 of the TPSm register, and CKm1 is selected via bits 7~4 of the TPSm register. In addition, only channel 1 and channel 3 can select CKm2 and CKm3, and CKm2 is selected via bits 9~8 of the TPSm register, and CKm3 is selected via bits 13 and 12 of the TPSm register.

The TPSm register in timer operation can only be rewritten in the following cases.

- If the PRSm00 to PRSm03 bits can be rewritten (n = 0 to 3):
   All channels for which CKm0 is selected as the operation clock (CKSmn1, CKSmn0 = 0, 0) are stopped (TEmn = 0).
- 2) If the PRSm10 to PRSm13 bits can be rewritten (n = 0 to 3): All channels for which CKm2 is selected as the operation clock (CKSmn1, CKSmn0 = 0, 1) are stopped (TEmn = 0).
- 3) If the PRSm20 and PRSm21 bits can be rewritten (n = 1, 3):
  All channels for which CKm1 is selected as the operation clock (CKSmn1, CKSmn0 = 1, 0) are stopped (TEmn = 0).
- 4) If the PRSm30 and PRSm31 bits can be rewritten (n = 1, 3):
  All channels for which CKm3 is selected as the operation clock (CKSmn1, CKSmn0 = 1, 1) are stopped (TEmn = 0).

The TPSm register can be set by a 16-bit memory manipulation instruction. Reset signal generation clears this register to 0000H.

| 1      | 1      | 1      | 1      | F <sub>CLK</sub> /2 <sup>15</sup>                            |

Note: Bit 15, 14, 11 and 10 must be set to "0".

#### Notice:

- 1. In case of changing the clock selected as F<sub>CLK</sub> (changing the value of the system clock control register (CKC)), the general-purpose timer unit must be stopped (TTm=0,100FH). The general-purpose timer unit needs to be stopped even when the operation clock (F<sub>MCK</sub>) is selected or when the active edge of the TImn pin input signal is used.
- 2. If F<sub>CLK</sub> (undivided) is selected as the operation clock (CKmk) and TDRnm is set to "0000H" (n=0, 1, m=0~3), the interrupt request of general-purpose timer unit cannot be used.
- 3. The clock waveform selected by the TPSm register is high for only 1  $F_{CLK}$  cycle from the rising edge. For details, refer to "5.5.1 Counting Clock ( $F_{TCLK}$ )".
- 4. F<sub>CLK</sub>: CPU/peripheral hardware clock frequency.

Note: Bits 15, 14, 11, 10 must be set to "0".

#### Notice:

- 1. The general-purpose timer unit (TTm=000FH) must be stopped if the clock selected as F<sub>CLK</sub> is changed (the value of the system clock control register (CKC) is changed). It is necessary to stop the general-purpose timer unit even when the operation clock (F<sub>MCK</sub>) is selected or when the active edge of the input signal to the TImn pin is selected.
- 2. oThe margin is within 5%.
- 3. F<sub>CLK</sub>: CPU/peripheral hardware clock frequency
- 4. Refer to "5.5.1 Counting Clock  $(F_{TCLK})$ " for details of the  $F_{CLK}$  /2" waveform selected for the TPSm register.

www.mcu.com.cn 103 / 624 Rev.1.0.3

## 5.3.3 Timer mode register mn (TMRmn)

The TMRmn register is the register that sets the operation mode of channel n. It performs the selection of the operation clock ( $F_{MCK}$ ), the selection of the count clock, the selection of master/slave, the selection of the 16-bit/8-bit timer (channel 1 and channel 3 of unit 0 only), the setting of the start trigger and the capture trigger, the selection of the effective edge of the timer input, and the operation modes (interval, capture, event counter, single count, capture & single count) settings.

It is prohibited to rewrite the TMRmn register during operation (TEmn=1). However, bit7 and bit6 (CISmn1, CISmn0) can be rewritten during part of the function operation (TEmn=1) (for details, refer to "5.8 Independent Channel Operation Function of General-Purpose Timer Unit" and "5.9 Multi-Channel Operation Function of General-Purpose Timer Unit").

The TMRmn register is set by a 16-bit memory manipulation instruction. After a reset signal is generated, the value of the TMRmn register changes to "0000H".

Remark: The bit11 of the TMRmn register varies from channel to channel.

TMRm2: MASTERmn bit (n=2).

TMRm1, TMRm3: SPLITmn bits (n=1, 3)

TMRm0: Fixed to "0".

| Other than the above  |           |           | Settings are disabled.              |   |                        |
| The operation of each mode varies depending on MDmn0 bit (see the table below). |           |           |                                     |   |                        |

| Operation mode (Value set by the MDmn3 to MDmn1 bits (see table above)) | MDmn0 | Setting of starting counting and interrupt   |
|---|-------|--|
| Interval timer mode (0, 0, 0)   | 0     | No timer interrupt is generated when counting starts (the output of the timer does not change).  |
| • Capture mode (0, 1, 0)  | 1     | A timer interrupt is generated when counting starts (the output of the timer also changes).  |
| • Event counter mode (0, 1, 1)  | 0     | No timer interrupt is generated when counting starts (the output of the timer does not change).  |
| Single count mode Note 2 (4, 0, 0)                                      | 0     | The start trigger in the count operation is invalid. No interruption at this time.   |
| • Single count mode Note 2 (1, 0, 0)                                    | 1     | The start trigger in the count operation is valid <sup>Note 3</sup> . No interruption at this time.  |
| Capture & single count mode (1, 1, 0)                                   | 0     | No timer interrupt is generated when counting starts (the output of the timer does not change). The start trigger in the count operation is invalid. No interruption at this time. |

Note 1: Bit11 is a read-only bit, fixed to "0", and write is ignored.

Note 2: In single count mode, the interrupt output (INTTMmn) and TOmn output at the start of counting are not controlled.

Note 3: If a start trigger is generated during operation (TSmn=1), the counter is initialized and counting is restarted (no interrupt request is generated).

Remark: m: unit number (m=0, 1) n: channel number (n=0~3)

www.mcu.com.cn 108 / 624 Rev.1.0.3

## 5.3.4 Timer status register mn (TSRmn)

The TSRmn register is a register that indicates the overflow status of the channel n counter.

The TSRmn register is valid only in capture mode (MDmn3~MDmn1=010B) and capture & single count mode (MDmn3~MDmn1=110B). Refer to Table 5-11 for the OVF bit changes and set/clear conditions in each operation mode.

The TSRmn register is read by a 16-bit memory manipulation instruction.

The lower 8 bits of the TSRmn register can be read with TSRmnL and 8-bit memory manipulation instructions. After a reset signal is generated, the value of the TSRmn register changes to "0000H".

Table 5-10: Table of timer status register mn (TSRmn)

| Symbol | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0   |
|--------|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|-----|
| TSRmn  | 0  | 0  | 0  | 0  | 0  | 0  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | OVF |

| OVF            | Counter overflow status of channel n   |  |  |  |  |  |  |  |  |  |  |
|----------------|--|--|--|--|--|--|--|--|--|--|--|
| 0              | No overflow occurred.  |  |  |  |  |  |  |  |  |  |  |
| 1              | Overflow occurred.   |  |  |  |  |  |  |  |  |  |  |
| If the OVF bit | If the OVF bit is "1", this flag is cleared when the next count does not overflow and the count value is captured (OVF=0). |  |  |  |  |  |  |  |  |  |  |

Table 5-11: OVF bit change and set/clear conditions in each operation mode

| Timer operation mode   | OVF bit | Set/clear conditions                 |  |  |  |  |  |  |
|--|---------|--------------------------------------|--|--|--|--|--|--|
| Capture mode   | Clear   | No overflow occurred at the capture. |  |  |  |  |  |  |
| Capture & single count mode                                    | Set     | Overflow occurred at the capture.    |  |  |  |  |  |  |
| Interval timer mode  | Clear   | _                                    |  |  |  |  |  |  |
| <ul><li>Event counter mode</li><li>Single count mode</li></ul> | Set     | (N/A)                                |  |  |  |  |  |  |

#### Remark:

- 1. m: unit number (m=0, 1) n: channel number (n=0~3)
- 2. Even if the counter overflows, the OVF bit does not change immediately, but changes on subsequent captures.

www.mcu.com.cn 109 / 624 Rev.1.0.3

## 5.3.5 Timer channel enable status register m (TEm)

The TEm register is a register that indicates the enable or stop status of each channel timer operation.

Each of the TEm register corresponds to each of the timer channel start register m (TSm) and timer channel stop register m (TTm). If each bit of the TSm register is "1", the corresponding bit of the TEm register is "1". If each bit of the TTm register is "1", the corresponding bit of the TTm register is cleared to "0".

The TEm register is read by a 16-bit memory manipulation instruction.

The lower 8 bits of the TEm register can be read with TEmL and 8-bit memory manipulation instructions. After a reset signal is generated, the value of the TEm register changes to "0000H".

Table 5-12: Table of timer channel enable status register m (TEm)

| Symbol | 15 | 14 | 13 | 12 | 11        | 10 | 9         | 8 | 7 | 6 | 5 | 4 | 3    | 2    | 1    | 0    |
|--------|----|----|----|----|-----------|----|-----------|---|---|---|---|---|------|------|------|------|
| TEm    | 0  | 0  | 0  | 0  | TEH<br>m3 | 0  | TEH<br>m1 | 0 | 0 | 0 | 0 | 0 | TEm3 | TEm2 | TEm1 | TEm0 |

| TEHm3 | Indication of whether operation of the higher 8-bit timer is enabled or stopped when channel 3 is in th 8-bit timer mode |  |  |  |  |  |  |  |  |
|-------|--|--|--|--|--|--|--|--|--|
| 0     | Operation is stopped.  |  |  |  |  |  |  |  |  |
| 1     | Operation is enabled.  |  |  |  |  |  |  |  |  |

| TEHm1 | Indication of whether operation of the higher 8-bit timer is enabled or stopped when channel 1 is in the 8-bit timer mode |
|-------|---|
| 0     | Operation is stopped.   |
| 1     | Operation is enabled.   |

| TEmn  | Indication of operation enable/stop status of channel n |  |  |  |  |  |  |  |  |  |
|---|---|--|--|--|--|--|--|--|--|--|
| 0   | Operation is stopped.                                   |  |  |  |  |  |  |  |  |  |
| 1   | Operation is enabled.                                   |  |  |  |  |  |  |  |  |  |
| This hit displays whather energing of the lower 9 hit timer for TEm1 and TEm2 is enabled as stopped when channel 1 or 2 is in |   |  |  |  |  |  |  |  |  |  |

This bit displays whether operation of the lower 8-bit timer for TEm1 and TEm3 is enabled or stopped when channel 1 or 3 is in the 8-bit timer mode.

Remark: m: unit number (m=0, 1) n: channel number (n=0~3)

www.mcu.com.cn 110 / 624 Rev.1.0.3

## 5.3.6 Timer channel start register m (TSm)

The TSm register is a trigger register that initializes the timer counter register mn (TCRmn) and sets the start of counting operation for each channel. If each bit is set to "1", the corresponding bit of the timer channel enable status register m (TEm) is set to "1". Since the TSmn bit, the TSHm1 bit and the TSHm3 bit are trigger bits, the TSmn bit, the TSHm1 bit and the TSHm3 bit are cleared immediately if the operation enbale state is changed (TEmn, TEHm1, TEHm3 = 1).

The TSm register is set by a 16-bit memory manipulation instruction.

The lower 8 bits of the TSm register can be set by TSmL and by an 8-bit memory manipulation instruction. After a reset signal is generated, the value of the TSm register changes to "0000H".

Table 5-13: Table of timer channel start register m (TSm)

| Symbol | 15 | 14 | 13 | 12 | 11        | 10 | 9         | 8 | 7 | 6 | 5 | 4 | 3    | 2    | 1    | 0    |
|--------|----|----|----|----|-----------|----|-----------|---|---|---|---|---|------|------|------|------|
| TSm    | 0  | 0  | 0  | 0  | TSH<br>m3 | 0  | TSH<br>m1 | 0 | 0 | 0 | 0 | 0 | TSm3 | TSm2 | TSm1 | TSm0 |

| TSHm3 | Trigger to enable (start) operation of the higher 8-bit timer when channel 3 is in the 8-bit timer mode |
|-------|---|
| 0     | No trigger operation.   |
|       | Set the TEHm3 bit to "1" to enter the counting enable state.  |
| 1     | If the counting of the TCRm3 register is started in the count enable state, the interval timer mode is  |
|       | entered (refer to Table 5-22 of "5.5.2 Start Timing of Counter").                                       |

| TSHm1 | Trigger to enable (start) operation of the higher 8-bit timer when channel 1 is in the 8-bit timer mode   |
|-------|---|
| 0     | No trigger operation.   |
| 1     | Set the TEHm1 bit to "1" to enter the counting enable state. If counting in the TCRm1 register is started in the count enable state, the interval timer mode is entered (refer to Table 5-22 of "5.5.2 Start Timing of Counter"). |

| TSmn | Operation enable (start) trigger of channel n  |
|------|--|
| 0    | No trigger operation.  |
| 1    | Set the TEmn bit to "1" to enter the counting enable state. The start of counting in the TCRmn register in the count enable state varies with each operation mode (refer to Table 5-22 of "5.5.2 Start Timing of Counter"). When channel 1 and channel 3 are in 8-bit timer mode, TSm1 and TSm3 are operation enable (start) triggers for the lower 8-bit timer. |

#### Notice:

- 1. Bits 15~12, 10, 8~4 must be set to "0".
- 2. When switching from a function that does not use Tlmn pin input to a function that uses Tlmn pin input, the following period of waiting is required from setting the timer mode register mn (TMRmn) until the TSmn bit is set to "1":
  - ① When the Tlmn pin noise filter is valid (TNFENmn=1): 4 operating clocks (F<sub>MCK</sub>)
  - ② When the TImn pin noise filter is invalid (TNFENmn=0): 2 operating clocks (F<sub>MCK</sub>)

#### Remark:

- 1. The TSm register always reads "0".
- 2. m: unit number (m=0, 1) n: channel number (n=0~3)

www.mcu.com.cn 111 / 624 Rev.1.0.3

## 5.3.7 Timer channel stop register m (TTm)

The TTm register is a trigger register to set the count stop of each channel.

If each bit is set to "1", the corresponding bit in the timer channel enable status register m (TEm) is cleared to "0". Since the TTmn bit, TTHm1 bit, and TTHm3 bit are trigger bits, the TTmn bit, TTHm1 bit, and TTHm3 bit are cleared immediately if the operation stop state is changed (TEmn, TEHm1, and TEHm3 = 0).

The TTm register is set by a 16-bit memory manipulation instruction.

The lower 8 bits of the TTm register can be set by TTmL and by an 8-bit memory manipulation instruction. After a reset signal is generated, the value of the TTm register changes to "0000H".

Table 5-14: Table of timer channel stop register m (TTm)

| Symbol | 15 | 14 | 13 | 12 | 11        | 10 | 9         | 8 | 7 | 6 | 5 | 4 | 3    | 2    | 1    | 0    |
|--------|----|----|----|----|-----------|----|-----------|---|---|---|---|---|------|------|------|------|
| TTm    | 0  | 0  | 0  | 0  | TTH<br>m3 | 0  | TTH<br>m1 | 0 | 0 | 0 | 0 | 0 | TTm3 | TTm2 | TTm1 | TTm0 |

| TTHm3 | Trigger to stop operation of the higher 8-bit timer when channel 3 is in the 8-bit timer mode |  |  |  |  |  |  |
|-------|---|--|--|--|--|--|--|
| 0     | No trigger operation  |  |  |  |  |  |  |
| 1     | TEHm3 bit is cleared to 0 and the count operation is stopped.                                 |  |  |  |  |  |  |

| TTHm1 | Trigger to stop operation of the higher 8-bit timer when channel 1 is in the 8-bit timer mode |  |  |  |  |  |  |
|-------|---|--|--|--|--|--|--|
| 0     | No trigger operation  |  |  |  |  |  |  |
| 1     | TEHm1 bit is cleared to 0 and the count operation is stopped.                                 |  |  |  |  |  |  |

| TTmn | Operation stop trigger of channel n  |
|------|--|
| 0    | No trigger operation   |
| 1    | TEmn bit clear to 0, to be count operation stop enable status.  This bit is the trigger to stop operation of the lower 8-bit timer for TTm1 and TTm3 when channel 1 or 3 is in the 8-bit timer mode. |

Notice: Bits 15~12, 10, 8~4 must be set to "0".

#### Remark:

- 1. The TTm register always reads "0".
- 2. m: unit number (m=0, 1) n: channel number (n=0~3)

www.mcu.com.cn 112 / 624 Rev.1.0.3

## 5.3.8 Timer input output select register (TIOS0)

The TIOS0 register is used to make selections for the inputs and outputs of unit 0. The timer inputs for channel 0 and channel 1 and the timer output for channel 2 of unit 0 are selected. The TIOS0 register is set by an 8-bit memory manipulation instruction. After a reset signal is generated, the value of the TIOS0 register changes to "00H".

Table 5-15: Table of timer input select register 0 (TIOS0)

| Addres | 0x40020474 | After reset: | R/W   |       |       |       |       |       |
|--------|------------|--------------|-------|-------|-------|-------|-------|-------|
| s:     |            | 00H          |       |       |       |       |       |       |
| Symbol | 7          | 6            | 5     | 4     | 3     | 2     | 1     | 0     |
| TIOS0  | TIS07      | TIS06        | TIS05 | TIS04 | TOS03 | TIS02 | TIS01 | TIS00 |

| TIS07 | TIS06 | TIS05 | Selection of timer input used for channel 0 |  |  |  |  |  |
|-------|-------|-------|---|--|--|--|--|--|
| 0     | 0     | 0     | Input signal for timer input pin (TI00)     |  |  |  |  |  |
| Other |       |       | Settings are disabled.                      |  |  |  |  |  |

| TIS04 | Selection of timer input used for channel 0 |  |  |  |  |  |  |  |
|-------|---|--|--|--|--|--|--|--|
| 0     | nput signal selected by TIS07~TIS05         |  |  |  |  |  |  |  |
| 1     | Event input signal of ELC                   |  |  |  |  |  |  |  |

| TOS03 | Enable channel 2 timer output      |  |  |  |  |  |  |  |
|-------|------------------------------------|--|--|--|--|--|--|--|
| 0     | utput enable                       |  |  |  |  |  |  |  |
| 1     | Output disable (output fixed to 0) |  |  |  |  |  |  |  |

| TIS02 | TIS01            | TIS00 | Selection of timer input used for channel 1           |  |  |  |  |  |
|-------|------------------|-------|---|--|--|--|--|--|
| 0     | 0                | 0     | Input signal for timer input pin (TI01)               |  |  |  |  |  |
| 0     | 0                | 1     | Event input signal of ELC                             |  |  |  |  |  |
| 0     | 1                | 0     | land dispelled times in put him (TIO4)                |  |  |  |  |  |
| 0     | 1                | 1     | Input signal to timer input pin (TI01)                |  |  |  |  |  |
| 1     | 0                | 0     | Low-speed on-chip oscillator clock (F <sub>IL</sub> ) |  |  |  |  |  |
| 1     | 0                | 1     | Subsystem clock (F <sub>SUB</sub> )                   |  |  |  |  |  |
|       | Other than above | e     | Settings are disabled.                                |  |  |  |  |  |

#### Notice:

- 1. The high-/low-level width of the selected timer inputs needs to be greater than or equal to  $1/F_{MCK}+10$ ns. Therefore, when  $F_{SUB}$  is selected as the  $F_{CLK}$  (CSS bit of the CKC register =1), the TIS02 bit cannot be set to "1".
- 2. When selecting the event input signal for ELC via timer input select register 0 (TIOS0), F<sub>CLK</sub> must be selected via timer clock select register 0 (TPS0).

www.mcu.com.cn 113 / 624 Rev.1.0.3

## 5.3.9 Timer output enable register m (TOEm)

The TOEm register is a register that sets to enable or disable the timer output of each channel. Channel n for which timer output has been enabled becomes unable to rewrite the value of the TOmn bit of timer output register m (TOm) described later by software, and the value reflecting the setting of the timer output function through the count operation is output from the timer output pin (TOmn).

The TOEm register is set by a 16-bit memory manipulation instruction.

The lower 8 bits of the TOEm register can be set by TOEmL and by an 8-bit memory manipulation instruction. After a reset signal is generated, the value of the TOEm register changes to "0000H".

Table 5-16: Table of timer output enable register m (TOEm)

| Symbol | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3         | 2         | 1         | 0         |
|--------|----|----|----|----|----|----|---|---|---|---|---|---|-----------|-----------|-----------|-----------|
| TOEm   | 0  | 0  | 0  | 0  | 0  | 0  | 0 | 0 | 0 | 0 | 0 | 0 | TOE<br>m3 | TOE<br>m2 | TOE<br>m1 | TOE<br>m0 |

| TOEmn | Enable/disbale the timer output of channel n  |
|-------|---|
| 0     | Disable timer output. The operation of the timer is not reflected to the TOmn bit, fixed output. The TOmn bit can be written and the level set by the TOmn bit is output from the TOmn pin. |
| 1     | Enable timer output.  The operation of the timer is reflected to the TOmn bit, producing an output waveform. The write of the TOmn bit is ignored.  |

Notice: Bit15~4 must be set to "0".

Remark: m: unit number (m=0, 1) n: channel number (n=0~3)

www.mcu.com.cn 114 / 624 Rev.1.0.3

## 5.3.10 Timer output register m (TOm)

The TOm register is a buffer register for each channel timer output.

The bit value of this register is output from the output pin (TOmn) of each channel timer.

The TOmn bit of this register can be rewritten by software only when timer output is disabled (TOEmn=0). When enabling the timer output (TOEmn=1), rewrite operations via software are ignored and its value is changed only by the operation of the timer.

To use the TI00/TO00, TI01/TO01, TI02/TO02, and TI03/TO03 pins as port functions, the corresponding TOmn bit must be set to "0".

The TOm register is set by a 16-bit memory manipulation instruction.

The lower 8 bits of the TOm register can be set by TOmL and by an 8-bit memory manipulation instruction. After a reset signal is generated, the value of the TOm register changes to "0000H".

Table 5-17: Table of timer output register m (TOm)

| Symb<br>ol | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3        | 2        | 1        | 0        |
|------------|----|----|----|----|----|----|---|---|---|---|---|---|----------|----------|----------|----------|
| TOm        | 0  | 0  | 0  | 0  | 0  | 0  | 0 | 0 | 0 | 0 | 0 | 0 | TOm<br>3 | TOm<br>2 | TOm<br>1 | TOm<br>0 |

| TOmn | Timer output of channel n             |  |  |  |  |  |
|------|---------------------------------------|--|--|--|--|--|
| 0    | he output value of the timer is "0".  |  |  |  |  |  |
| 1    | The output value of the timer is "1". |  |  |  |  |  |

Notice: Bit15~4 must be set to "0".

Remark: m: unit number (m=0, 1) n: channel number (n=0~3)

www.mcu.com.cn 115 / 624 Rev.1.0.3

## 5.3.11 Timer output level register m (TOLm)

The TOLm register is a register that controls the output level of each channel timer.

When timer output (TOEmn=1) is enabled and the multi-channel linkage operation function (TOMmn=1) is used, the set and reset timing of the timer output signal reflects the inverse setting of each channel n performed by this register. In the master channel output mode (TOMmn=0), this register setting is invalid.

The TOLm register is set by a 16-bit memory manipulation instruction.

The lower 8 bits of the TOLm register can be set by TOLmL and by an 8-bit memory manipulation instruction. After a reset signal is generated, the value of the TOLm register changes to "0000H".

Table 5-18: Table of timer output level register m (TOLm)

| Symbol | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3         | 2         | 1         | 0 |
|--------|----|----|----|----|----|----|---|---|---|---|---|---|-----------|-----------|-----------|---|
| TOLm   | 0  | 0  | 0  | 0  | 0  | 0  | 0 | 0 | 0 | 0 | 0 | 0 | TOL<br>m3 | TOL<br>m2 | TOL<br>m1 | 0 |

| TOLmn | Control of timer output level of channel n |  |  |  |  |
|-------|--|--|--|--|--|
| 0     | ositive logic output (active-high)         |  |  |  |  |
| 1     | Inverted output (active-low)               |  |  |  |  |

#### Notice:

- 1. Bit15~4 and bit0 must be set to "0".
- 2. If the value of this register is rewritten while the timer is operating, the timer output logic is inverted at the next time the timer output signal changes, rather than immediately after the rewrite.

Remark: m: unit number (m=0, 1) n: channel number (n=0~3)

www.mcu.com.cn 116 / 624 Rev.1.0.3

## 5.3.12 Timer output mode register m (TOMm)

The TOMm register is a register that controls the output mode of each channel timer. When used as an independent channel operation function, the corresponding bit of the using channel should be set to "0".

When used as a multi-channel linkage operation function (PWM output, single trigger pulse output and multiple PWM output), the corresponding bit of the master channel is "0" and the corresponding bit of the slave channel is "1".

When the timer output (TOEmn=1) is enabled, the setting of each channel n is reflected in this register during the setting and reseting timing of the timer output signal.

The TOMm register is set by a 16-bit memory manipulation instruction.

The lower 8 bits of the TOMm register can be set by TOMmL and by an 8-bit memory manipulation instruction. After a reset signal is generated, the value of the TOMm register changes to "0000H".

Table 5-19: Table of timer output mode register m (TOMm)

| Symbol | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3         | 2         | 1         | 0 |
|--------|----|----|----|----|----|----|---|---|---|---|---|---|-----------|-----------|-----------|---|
| TOMm   | 0  | 0  | 0  | 0  | 0  | 0  | 0 | 0 | 0 | 0 | 0 | 0 | TOM<br>m3 | TOM<br>m2 | TOM<br>m1 | 0 |

| TOMmn | Control of channel n timer output mode   |
|-------|--|
| 0     | Master channel output mode (alternate output via timer interrupt request signal (INTTMmn))   |
| 1     | Slave channel output mode (output is set via timer interrupt request signal (INTTMmn) of master channel and output is reset via timer interrupt request signal (INTTMmp) of slave channel) |

Notice: Bit15~4 and bit0 must be set to "0".

Remark: m: unit number (m=0, 1) n: channel number n=0~3 (master channel: n=0, 2) p: slave channel number (n=0: p=1, 2, 3 n=2: p=3) (for details on the relationship between the master channel and the slave channel, refer to "5.4.1 Basic Rules for Multi-Channel Linkage Operation Function".)

www.mcu.com.cn 117 / 624 Rev.1.0.3

## 5.3.13 Noise filter enable register 1 (NFEN1)

The NFEN1 register sets whether the noise filter is used for the input signals of the timer input pins of each channel of Unit 0. For pins that require noise removal, the corresponding bit must be set to "1" to make the noise filter effective. When the noise filter is enabled, after synchronization with the operating clock ( $F_{MCK}$ ) for the target channel, whether the signal keeps the same value for two clock cycles is detected. When the noise filter is disabled, the input signal is only synchronized with the operating clock ( $F_{MCK}$ ) for the target channel Note.

The NFEN1 register is set by an 8-bit memory manipulation instruction. After a reset signal is generated, the value of the NFEN1 register changes to "00H".

Table 5-20: Table of noise filter enable register 1 (NFEN1)

| Address: 0x4 | 0040471 |   |   |   |         |         |         |         |

| 1       | Noise filter ON                                |

| TNFEN00 | Usage of input signal noise filter on TI00 pin |
|---------|--|
| 0       | Noise filter OFF                               |
| 1       | Noise filter ON                                |

#### Remark:

- 1. For details, refer to "5.5.1(2) When the valid edge of Tlmn pin input signal (CCSmn=1) is selected", "5.5.2 Start Timing of Counter ", and "5.7 Control of Timer Input (Tlmn)".
- 2. Refer to "Chapter 2 Port Function" for the configuration of timer input/output pins of channels 0~3.

www.mcu.com.cn 118 / 624 Rev.1.0.3

# 5.3.14 Noise filter enable register 2 (NFEN2)

The NFEN2 register sets whether the noise filter is used for the input signals of the timer input pins of each channel of Unit 1. For pins that require noise removal, the corresponding bit must be set to "1" to make the noise filter effective. When the noise filter is enabled, after synchronization with the operating clock ( $F_{MCK}$ ) for the target channel, whether the signal keeps the same value for two clock cycles is detected. When the noise filter is disabled, the input signal is only synchronized with the operating clock ( $F_{MCK}$ ) for the target channel Note.

The NFEN2 register is set by an 8-bit memory manipulation instruction. After a reset signal is generated, the value of the NFEN2 register changes to "00H".

Table 5-21: Table of noise filter enable register 2 (NFEN2)

| Address: 0x4 | 0040472 |   |   |   | are regions. | _ (: :: _: -, |         |         |

www.mcu.com.cn 119 / 624 Rev.1.0.3

## 5.3.15 Registers controlling port functions of timer input/output pins

When using the general-purpose timer unit, the input/output pins of Timer0/Timer1 can be arbitrarily configured to each port except RESETB. For details, refer to "Chapter 2 Port Function".

When multiplexing the output pins of Timer0/Timer1 to a port, you must set the bits of the port mode control register (PMCxx) and the port mode register (PMxx) corresponding to that port to "0", and set the port multiplexing function configuration register (PxxCFG). At this time, the bit of the port register (Pxx) can be "0" or "1".

(Example) When P21 is configured as TO10 and used as a timer output

Set the PMC21 bit of port mode control register 2 to "0".

Set bit PM21 of port mode register 2 to "0".

Set port output multiplexing function configuration register P21CFG to "0x12".

When using the multiplexed ports of the Timer0/Timer1 input pins as timer inputs, you must set the bit of the port mode register (PMxx) corresponding to each port to "1" and the bit of the port mode control register (PMCxx) to "0", and set the port multiplexing function configuration register (PxxCFG). At this time, the bit of the port register (Pxx) can be "0" or "1".

(Example) When P20 is configured as TI10 and used as a timer output

Set the PMC20 bit of port mode control register 2 to "0".

Set bit PM20 of port mode register 2 to "0".

Set port output multiplexing function configuration register P20CFG to "0x0a".

## 5.4 Basic rules of general-purpose timer unit

### 5.4.1 Basic rules of multi-channel linkage operation function

The multi-channel linkage function is a function that combines a master channel (a reference timer that counts cycles) and a slave channel (a timer that operates in compliance with the master channel), and several rules need to be observed when using it.

The basic rules of the multi-channel linkage operation function are shown below.

- 1) Only the even-number channel (channel 0, channel 2) can be set as a master channel.
- 2) Any channel other than channel 0 can be set as a slave channel.
- 3) Only the lower channel of the master channel can be set as a slave channel. For example, when setting channel 0 as the master channel, it is possible to set the channels starting from channel 1 (channels 1 to 3) as slave channels.
- 4) Multiple slave channels can be set for 1 master channel.
- 5) When multiple master channels are used, slave channels that span the master channel cannot be set.
  - For example, when setting channel 0 and channel 2 as the master channel, channel 1 can be set as the slave channel of master channel 0, but channel 3 cannot be set as the slave channel of master channel 0.
- 6) The slave channels linked to the master channel need to be set to the same operating clock. The CKSmn0 bit and CKSmn1 bit (bit15 and bit14 of Timer Mode Register mn (TMRmn)) of the slave channel linked to the master channel need to be the same setting value.
- 7) The master channel can pass the INTTMmn (interrupt), start software trigger and count clock to the lower channel.
- 8) The slave channel can use the master channel's INTTMmn (interrupt), start software trigger, and count clocks as source clocks, but cannot pass its own INTTMmn (interrupt), start software trigger, and count clocks to the lower channel.
- 9) The master channel cannot use the INTTMmn (interrupt), start software trigger and count clocks of other high master channels as source clocks.
- 10) In order to start the channels to be linked at the same time, the channel start trigger bit (TSmn) of the linked channel needs to be set at the same time.
- 11) Only all linked channels or the master channel can use the setting of the TSmn bit in the counting operation. It is not possible to use the setting of the TSmn bit of the slave channel only.
- 12) In order to stop the linked channels at the same time, the channel stop trigger bit (TTmn) of the linked channel needs to be set at the same time.
- 13) In linked operation, CKm2/CKm3 cannot be selected because the master and slave channels need the same operating clock.
- 14) The timer mode register m0 (TMRm0) has no master bit and is fixed to "0". However, since channel 0 is the highest bit channel, it can be used as the master channel during linkage operation.

The basic rules of the multi-channel linkage operation function are the rules applicable to the group of channels (a collection of master and slave channels that form a multi-channel linkage operation function).

If you set 2 or more channel groups that are not linked to each other, the above basic rules do not apply to the channel groups.

Remark: m: unit number (m=0, 1) n: channel number (n=0~3)

www.mcu.com.cn 122 / 624 Rev.1.0.3

# 5.4.2 Basic rules of 8-bit timer operation function (channels 1 and 3 of unit 0 only)

The 8-bit timer operation function makes it possible to use a 16-bit timer channel in a configuration consisting of two 8-bit timer channels.

This function can only be used for channels 1 and 3, and there are several rules for using it.

The basic rules for this function are as follows:

- 1) The 8-bit timer operation function applies only to channels 1 and 3.
- When using 8-bit timers, set the SPLIT bit of timer mode register mn (TMRmn) to 1.
- 3) The higher 8 bits can be operated as the interval timer function.
- 4) At the start of operation, the higher 8 bits output INTTMm1H (an interrupt) (which is the same operation performed when MDmn0 is set to 1).
- 5) The operation clock of the higher 8 bits is selected according to the CKSmn1 and CKSmn0 bits of the lower-bit TMRmn register.
- 6) For the higher 8 bits, the TSHm1/TSHm3 bit is manipulated to start channel operation and the TTHm1/TTHm3 bit is manipulated to stop channel operation. The channel status can be checked using the TEHm1/TEHm3 bit.
- 7) The lower 8 bits operate according to the TMRmn register settings. The following three functions support operation of the lower 8 bits:
  - 1 Interval timer function
  - 2 External event counter function
  - 3 Delay count function
- 8) For the lower 8 bits, the TSm1/TSm3 bit is manipulated to start channel operation and the TTm1/TTm3 bit is manipulated to stop channel operation. The channel status can be checked using the TEm1/TEm3 bit.
- 9) During 16-bit operation, manipulating the TSHm1, TSHm3, TTHm1, and TTHm3 bits is invalid. The TSm1, TSm3, TTm1, and TTm3 bits are manipulated to operate channels 1 and 3. The TEHm3 and TEHm1 bits are not changed.
- 10) For the 8-bit timer function, the linkage operation functions (single pulse, PWM, and multiple PWM) cannot be used.

Remark: unit number (m=0) n: channel number (n=1, 3)

www.mcu.com.cn 123 / 624 Rev.1.0.3

## 5.5 Operation of counter

## 5.5.1 Count clock (F<sub>TCLK</sub>)

The count clock of the general-purpose timer unit  $(F_{TCLK})$  can be selected by the CCSmn bit of the timer mode register mn (TMRmn) for any of the following clocks:

- ① The CKSmn0 bit and CKSmn1 bit specified operation clock (F<sub>MCK</sub>)
- 2 The active edge of the Tlmn pin input signal

The general-purpose timer unit is designed to operate synchronously with  $F_{CLK}$ , so the timing of the count clock  $(F_{TCLK})$  is as follows.

(1) When operation clock  $(F_{MCK})$  specified by the CKSmn0 and CKSmn1 bits is selected (CCSmn = 0)

According to the setting of timer clock selection register m (TPSm), the counting clock ( $F_{TCLK}$ ) is  $F_{CLK} \sim F_{CLK}$  /2<sup>15</sup>. However, when the frequency division of  $F_{CLK}$  is selected, the clock selected by TPSm register is a signal that has only 1  $F_{CLK}$  cycle of high level from the rising edge. When  $F_{CLK}$  is selected, it is fixed to high level.

In order to obtain synchronization with  $F_{CLK}$ , timer count register mn (TCRmn) delays the counting by one  $F_{CLK}$  clock from the rising edge of the counting clock, which is called "counting at the rising edge of the counting clock" for convenience.

Remark:  $\triangle$ : Rising edge of the count clock

▲: Synchronization, increment/decrement of counter

F<sub>CLK</sub>: CPU/peripheral hardware clock

www.mcu.com.cn 124 / 624 Rev.1.0.3

(2) When valid edge of input signal via the Tlmn pin is selected (CCSmn = 1)

The count clock ( $F_{TCLK}$ ) is a signal that detects an active edge of the Tlmn pin input signal and is synchronized with the next  $F_{MCK}$  rising edge. In fact, this is a signal delayed by 1~2  $F_{MCK}$  clocks compared to the input signal of the Tlmn pin (delay 3~4  $F_{MCK}$  clocks when using noise filters). In order to obtain synchronization with  $F_{CLK}$ , the timer count register mn (TCRmn) delays the count by one  $F_{CLK}$  time from the rising edge of the count clock, which is referred to as "counting at the effective edge of the Tlmn pin input signal" for convenience.

F<sub>CLK</sub>

## 5.5.2 Start timing of counter

The timer count register mn (TCRmn) enters the operation enable state by setting TSmn bit of the timer channel start register m (TSm).

Execution from the counting enable state to the start of the timer count register mn (TCRmn) is shown in Table 5-22.

Table 5-22: Operation from the counting enable state to the start of the timer count register mn (TCRmn)

| Timer operation mode                    | Operation after setting TSmn bit to "1"  |
|---|--|
|   | No operation is performed from the detection of the start trigger (TSmn=1) until the count clock is generated.   |
| <ul> <li>Interval timer mode</li> </ul> | The value of the TDRmn register is loaded into the TCRmn register by the first count clock   |
|   | and decremented by subsequent count clocks (refer to "5.5.3(1) Operation of the interval timer mode").   |
|   | The value of the TDRmn register is loaded into the TCRmn register by writing a "1" to the TSmn bit.  |
| Event counter mode                      | If the input edge of TImn is detected, the count is decremented by the subsequent count clocks. (Refer to "5.5.3(2) Operation of the event counter mode").                           |
|   | No operation is performed from the time the start trigger is detected until the count clock is generated.  |
| Capture mode                            | The "0000H" is loaded into the TCRmn register by the first count clock, and incremental  |
| Capture mode                            | counting is performed by the subsequent count clocks (refer to "5.5.3(3) Operation of the capture mode (input pulse interval measurement)").   |
|   | By writing "1" to the TSmn bit while the timer is stopped (TEmn=0), it enters the wait state for   |
| Oin als second asseds                   | the start of the trigger. No operation is performed from the time the start trigger is detected until  |
| Single count mode                       | the count clock is generated. The value of the TDRmn register is loaded into the TCRmn register by the first count clock, and decremental counting by subsequent count clocks (refer |
|   | to "5.5.3(4) Operation of the single count mode").   |
|   | By writing "1" to the TSmn bit while the timer is stopped (TEmn=0), it enters the wait state for   |
| Capture & single count                  | the start of the trigger. No operation is performed from the time the start trigger is detected until  |
| mode                                    | the count clock is generated. The "0000H" is loaded into the TCRmn register by the first count   |
|   | clock, and incremental counting is performed by the subsequent count clocks (refer to "5.5.3(5) Operation of capture & single count mode (measurement of high-level width").         |
|   | Operation of capture & single count mode (measurement of night-level water).   |

www.mcu.com.cn 126 / 624 Rev.1.0.3

## 5.5.3 Operation of counter

The following describes the counter operation for each mode.

- (1) Operation of interval timer mode
  - ① The operation enable state is entered by writing "1" to the TSmn bit (TEmn=1). The timer count register mn (TCRmn) remains at its initial value until a count clock is generated.
  - ② A start trigger signal is generated by enabling the 1st count clock (F<sub>MCK</sub>) after the operation.
  - ③ When MDmn0 bit is "1", INTTMmn is generated by the start trigger signal.
  - 4 The value of timer data register mn (TDRmn) is loaded into the TCRmn register by enabling the 1st count clock after the operation, and counting starts in interval timer mode.
  - (5) If the TCRmn register decrements to "0000H", INTTMmn is generated by the next count clock (F<sub>MCK</sub>) and continues counting after loading the value of timer data register mn (TDRmn) into the TCRmn register.

Remark:

- In the first cycle operation of count clock after writing the TSmn bit, an error at a maximum of
  one clock is generated since count start delays until count clock has been generated. When the
  information on count start timing is necessary, an interrupt can be generated at count start by
  setting MDmn0 = 1.
- 2.  $F_{MCK}$ , the start trigger detection signal, and INTTMmn become active between one clock in synchronization with  $F_{CLK}$ .

www.mcu.com.cn 127 / 624 Rev.1.0.3

- (2) Operation of event counter mode
  - ① The timer count register mn (TCRmn) holds its initial value while operation is stopped (TEmn=0).
  - ② The operation enable state is enabled by writing "1" to the TSmn bit (TEmn=1).
  - ③ The value of timer data register mn (TDRmn) is loaded into the TCRmn register while both the TSmn and TEmn bits are changed to "1" and counting begins.

Thereafter, the value of the TCRmn register is counted decreasingly by the count clock at the active edge of the Tlmn input.

Figure 5-6: Operation timing (event counter mode)

Remark: This is a timing without the noise filter. If the noise filter is used, the edge detection is delayed by 2 more  $F_{MCK}$  cycles (3~4 cycles in total) from the Tlmn input. The 1 cycle error is because the Tlmn input is not synchronized with the count clock ( $F_{MCK}$ ).

www.mcu.com.cn 128 / 624 Rev.1.0.3

- (3) Operation of capture mode (interval measurement of input pulses)
  - ① The operation enable state is entered by writing "1" to the TSmn bit (TEmn=1).
  - ② The timer count register mn (TCRmn) remains at its initial value until a count clock is generated.
  - 3 A start trigger signal is generated by enabling the 1st count clock (F<sub>MCK</sub>) after the operation. Then, the "0000H" is loaded into the TCRmn register and counting starts in capture mode (INTTMmn is generated by the start trigger signal when MDmn0 bit is "1").
  - 4 If an active edge of TImn input is detected, the value of TCRmn register is captured to TDRmn register and INTTMmn interrupt is generated. The capture value is meaningless at this point. The TCRmn register continues counting from the "0000H".
  - ⑤ If an active edge of the next Tlmn input is detected, the value of the TCRmn register is captured to the TDRmn register and the INTTMmn interrupt is generated.

Figure 5-7: Operation timing (capture mode: interval measurement of input pulses)

- Note 1: When the clock is input to Tlmn (with trigger) before the start, the count is started by detecting the trigger even if no edge is detected, so the capture value at the 1st capture (④) is not a pulse interval (in this example, 0001: 2 clock intervals) and must be ignored.
- Note 2: Because the 1st count clock cycle runs after the TSmn bit is written and delays the start of counting before generating the count clock, an error of up to 1 clock cycle is generated. Also, if you need information about the start of the count timing, set MDmn0 to "1" so that an interrupt can be generated at the start of the count.
- Remark: This is a timing without the noise filter. If the noise filter is used, the edge detection is delayed by 2 more F<sub>MCK</sub> cycles (3~4 cycles in total) from the TImn input. The 1 cycle error is because the TImn input is not synchronized with the count clock (F<sub>MCK</sub>).

www.mcu.com.cn 129 / 624 Rev.1.0.3

#### (4) Operation of single count mode

- ① The operation enable state is entered by writing "1" to the TSmn bit (TEmn=1).
- 2 The timer count register mn (TCRmn) remains the initial value until a start trigger signal is generated.
- ③ Detects the rising edge of the Tlmn input.
- 4 The value (m) of the TDRmn register is loaded into the TCRmn register after a start trigger signal is generated, and counting begins.
- (5) When the TCRmn register decrements to "0000H", the INTTMmn interrupt is generated and the value of TCRmn register changes to "FFFFH" and stop counting.

Remark: This is a timing without the noise filter. If the noise filter is used, the edge detection is delayed by 2 more F<sub>MCK</sub> cycles (3~4 cycles in total) from the Tlmn input. The 1 cycle error is because the Tlmn

input is not synchronized with the count clock (F<sub>MCK</sub>).

www.mcu.com.cn 130 / 624 Rev.1.0.3

- (5) Operation of capture & single count mode (measurement of high-level width)
  - ① The operation enable state is entered by writing "1" to the TSmn bit of the timer channel start register m (TSm)(TEmn=1).
  - ② The timer count register mn (TCRmn) remains the initial value until a start trigger signal is generated.
  - 3 Detects the rising edge of the Tlmn input.
  - 4 After the start trigger signal is generated, "0000H" is loaded into the TCRmn register and counting starts.
  - ⑤ If the falling edge of TImn input is detected, the value of the TCRmn register is captured to the TDRmn register and an INTTMmn interrupt is generated.

Figure 5-9: Operation timing (capture & single count mode: measurement of high-level width)

Remark: This is a timing without the noise filter. If the noise filter is used, the edge detection is delayed by 2 more  $F_{MCK}$  cycles (3~4 cycles in total) from the Tlmn input. The 1 cycle error is because the Tlmn input is not synchronized with the count clock ( $F_{MCK}$ ).

TOLmn TOMmn

Interrupt signal of master channel
(INTTMmn)

set

reset/swap

Tomn register

set

Tomn pin

Tomn pin

TOEmn

Figure 5-10: Output circuit configuration

The following explains the output circuit of the TOmn pin.

- ① When the TOMmn bit is "0" (master channel output mode), the setting value of timer output level register m (TOLm) is ignored and only INTTMmp (slave channel timer interrupt) is passed to timer output register m (TOm).
- ② When the TOMmn bit is "1" (slave channel output mode), INTTMmn (master channel timer interrupt) and INTTMmp (slave channel timer interrupt) are passed to the TOm register.
  - At this time, the TOLm register becomes valid and the signals are controlled as follows:
  - When TOLmn = 0: Positive logic output (INTTMmn → set, INTTMmp → reset)
  - When TOLmn = 1: Negative logic output (INTTMmn → reset, INTTMmp → set)
  - When INTTMmn and INTTMmp are simultaneously generated, (0% output of PWM), INTTMmp (reset signal) takes priority, and INTTMmn (set signal) is masked.
- ③ In the state of enabling timer output (TOEmn=1), INTTMmn (master channel timer interrupt) and INTTMmp (slave channel timer interrupt) are passed to TOm register. Writing to the TOm register (TOmn write signal) is invalid.
  - When the TOEmn bit is "1", the output of the TOmn pin is not changed except for the interrupt signal. To initialize the output level of the TOmn pin, you need to write a value to the TOm register after setting it to disable the timer output (TOEmn=0).
- Writing to the TOmn bit for the object channel (TOmn write signal) is valid when the timer output is disabled (TOEmn=0). When the timer output is disabled (TOEmn=0), INTTMmn (master channel timer interrupt) and INTTMmp (slave channel timer interrupt) are not passed to the TOm register.
- ⑤ The TOm register can be read at any time and the output level of the TOmn pin can be confirmed.

Remark: m: unit number (m= 0,1) n: channel number n=0~3 (master channel: n=0, 2) p: slave channel number (n=0: p=1, 2, 3 n=2: p=3)

## 5.6.2 TOmn pin output setting

The following figure shows the procedure and status transition of the TOmn output pin from initial setting to timer operation start.

Figure 5-11: State change from setting timer output to start of operation

- ① Set the operation mode of the timer output.
  - TOMmn bit (0: master channel output mode, 1: slave channel output mode)
  - TOLmn bit (0: positive logic output, 1: negative logic output)
- ② The timer output signal is set to the initial state by setting the timer output register m (TOm). Writing "1" to TOEmn bit enables timer output (writing to TOm register is disabled).
- ③ The port is set to digital input/output via the port mode control register (PMCxx)
- 4 Set the input/output of the port to output
- ⑤ Enable timer operation (TSmn=1).

Remark: m: unit number (m=0, 1) n: channel number (n=0~3)

www.mcu.com.cn 133 / 624 Rev.1.0.3

## 5.6.3 Cautions for channel output operation

(1) Change of setting values for TOm, TOEm, TOLm, TOMm registers in timer operation The operation of the timer (timer count register mn (TCRmn) and timer data register mn (TDRmn)) and the Tomn output circuit are independent. Therefore, changes in the setting values of timer output register m (TOm), timer output enable register m (TOEm), and timer output level register m (TOLm) do not affect the operation of the timer, and the setting values can be changed during timer operation. However, in order to output the expected waveform from the TOmn pin during the operation of each timer, the value must be set to the example of the register setting contents for each operation shown in 5.8 and 5.9.

If the setting values of TOEm register and TOLm register other than TOm register are changed before and after generating the timer interrupt (INTTMmn) signal for each channel, the waveform output from TOmn pin may be different depending on whether it is changed before or after generating the timer interrupt (INTTMmn) signal.

- (2) Default level of TOmn pin and output level after timer operation start

  The change in the output level of the TOmn pin when timer output register m (TOm) is written while timer output is disabled (TOEmn = 0), the initial level is changed, and then timer output is enabled (TOEmn = 1) before port output is enabled, is shown below.
  - ① Operation starts in master channel output mode (TOMmn=0)
    In the master channel output mode (TOMmn=0), the setting of the timer output level register m (TOLm) is invalid. If the timer operation is started after the initial level is set, the output level of the TOmn pin is inverted by generating an alternate signal.

Figure 5-12: Output state of TOmn pin at alternate output (TOMmn=0)

#### Remark:

- 1. Toggle: Reverse TOmn pin output status.
- 2. m: unit number (m=0, 1) n: channel number (n=0~3)

www.mcu.com.cn 134 / 624 Rev.1.0.3

② When operation starts with slave channel output mode (TOMmn = 1) setting (PWM output))
In slave channel output mode (TOMmn=1), the active level depends on the setting of timer output level register m (TOLmn).

**TOEmn** valid voltage level valid voltage level valid voltage level initial Hi-Z TOmp=0 state (initial state: low) TOLmp=0 (valid high voltage level) TOmp=1 (initial state: high) TOmP (output) TOmp=0 (initial state: low) TOLmp=1 (valid low voltage level) TOmp=1 (initial state: high)

www.mcu.com.cn 135 / 624 Rev.1.0.3

#### (3) Operation of TOmn pin in slave channel output mode (TOMmn = 1)

① When timer output level register m (TOLm) setting has been changed during timer operation When the TOLm register setting has been changed during timer operation, the setting becomes valid at the generation timing of the TOmn pin change condition. Rewriting the TOLm register does not change the output level of the TOmn pin.

The operation when TOMmn is set to 1 and the value of the TOLm register is changed while the timer is operating (TEmn = 1) is shown below.

Figure 5-14: Operation when the contents of the TOLm register are changed during timer operation

#### ② Set/reset timing

In order to achieve 0% and 100% output at PWM output, the set timing of the TOmn pin/TOmn bit when generating the master channel timer interrupt (INTTMmn) is delayed by 1 count clock via the slave channel.

When the set condition and reset condition are generated at the same time, the reset condition is given priority.

The set/reset operation status when setting the master/slave channel according to the following method is shown in Figure 5-15.

Master channel: TOEmn=1, TOMmn=0, TOLmn=0 Slave channel: TOEmp=1, TOMmp=1, TOLmp=0

## 5.6.4 One-time operation of TOmn bit

Like the timer channel start register m (TSm), the timer output register m (TOm) has the set bits (TOmn) for all channels and can therefore operate the TOmn bits for all channels at once.

Table 5-23: One-time operation example of TO0n bit

| Before writing   |   |   |   |   |   |   |   |   |   |   |   |   |   |     |       |      |      |       |
|--|---|---|---|---|---|---|---|---|---|---|---|---|---|-----|-------|------|------|-------|

### 5.6.5 Timer interrupt and TOmn pin output when counting starts

In interval timer mode or capture mode, the MDmn0 bit of timer mode register mn (TMRmn) is the bit that sets whether to generate a timer interrupt when counting starts.

When the MDmn0 bit is "1", the start timing of the count can be known by generating a timer interrupt (INTTMmn). In other modes, the timer interrupt and TOmn output at the start of counting are not controlled. An example of operation when set to interval timer mode (TOEmn=1, TOMmn=0) is shown below.

Figure 5-17: An operation example of timer interrupt and TOmn output at start count

#### (a) When MDmn0 = 1

#### (b) When MDmn0 = 0

When MDmn0 bit is "1", the timer interrupt (INTTMmn) is output at the start of counting and TOmn is output alternately.

When MDmn0 bit is "0", no timer interrupt (INTTMmn) is output at the start of counting and TOmn is not changed, while INTTMmn is output and TOmn is alternately output after 1 cycle of counting.

Remark: m: unit number (m=0, 1) n: channel number (n=0~3)

www.mcu.com.cn 140 / 624 Rev.1.0.3

# 5.7 Control of timer input (TImn)

## 5.7.1 Structure of Tlmn pin input circuit

The signal from the timer input pins is input to the timer control circuit via a noise filter and the edge detection circuit. For pins that need to be removed from noise, the corresponding pin noise filter must be set to enable. The block diagram of the input circuit is as follows.

Figure 5-18: Structure of input circuit

www.mcu.com.cn 141 / 624 Rev.1.0.3

#### 5.7.2 Noise filter

When the noise filter is inactive, synchronization is performed only by the operation clock ( $F_{MCK}$ ) of channel n. When the noise filter is active, 2 clocks are detected after synchronization by the operation clock ( $F_{MCK}$ ) of channel n. The waveform of the TM4mn input pin after the noise filter circuit with the noise filter ON or OFF is shown below.

Figure 5-19: Sample waveform of Tlmn input pin with noise filter ON or OFF

Notice: The input waveform on the Tlmn pin is used to illustrate the operation of the noise filter is ON or OFF. For actual operation, the input must be made in accordance with the Tlmn input high- and low-level width shown in AC characteristics.

www.mcu.com.cn 142 / 624 Rev.1.0.3

## 5.7.3 Cautions on channel input operation

When set to not use the timer input pin, no operating clock is provided to the noise filter circuit. Therefore, the following wait time is required from the time set to use the timer input pin to the time the channel corresponding to the timer input pin is set to operate the enable trigger.

#### (1) Noise filter OFF

When bits 12 (CCSmn), 9 (STSmn1), and 8 (STSmn0) in the timer mode register mn (TMRmn) are 0 and then one of them is set, wait for at least two cycles of the operating clock (F<sub>MCK</sub>), and then set the operation enable trigger bit in the timer channel start register (TSm).

#### (2) Noise filter ON

When bits 12 (CCSmn), 9 (STSmn1), and 8 (STSmn0) in the timer mode register mn (TMRmn) are all 0 and then one of them is set, wait for at least four cycles of the operating clock ( $F_{MCK}$ ), and then set the operation enable trigger bit in the timer channel start register (TSm).

# 5.8 Independent channel operation function of general-purpose timer unit

## 5.8.1 Operation as interval timer/square wave output

#### (1) Interval timer

It can be used as a reference timer to generate INTTMmn (timer interrupt) at fixed intervals. The interrupt generation period can be calculated using the following equation:

INTTMmn (timer interrupt) generation period = count clock period × (TDRmn set value +1)

#### (2) Operation as square wave output

The TOmn alternates outputs while generating the INTTMmn, outputting a square wave with a 50% duty cycle.

The period and frequency of the square wave can be calculated using the following equation:

Period of square wave output from TOmn = Period of count clock  $\times$  (TDRmn set value +1)  $\times$  2

Frequency of square wave output from TOmn = Frequency of count clock /  $\{(TDRmn \text{ set value } +1) \times 2\}$ 

In the interval timer mode, the timer count register mn (TCRmn) is used as a decrement counter.

After setting the channel start trigger bit (TSmn, TSHm1, TSHm3) of the timer channel start register m (TSm) to "1", the value of timer data register mn (TDRmn) is loaded into the TCRmn register by the first count clock. At this time, if the MDmn0 bit of the timer mode register n (TMRmn) is "0", INTTMmn is not output and TOmn is not alternately output. If the MDmn0 bit of TMRmn register is "1", INTTMmn is output and TOmn is alternately output. Then, the TCRmn register is decremented by the count clock.

If the TCRmn becomes "0000H", the INTTMmn and TOmn are output alternately by the next count clock. At the same time, the value of TDRmn register is loaded into TCRmn register again. After that, continue the same operation.

The TDRmn register can be rewritten at any time, and the rewritten TDRmn register value is valid from the next cycle.

# 5.8.2 Operation as external event counter

It can be used as an event counter to count the active edges (external events) detected on the Tlmn pin input and generate an interrupt if the specified count value is reached. The specified count value can be calculated using the following equation:

In the event counter mode, the timer count register mn (TCRmn) is used as a decrement counter.

The value of timer data register mn (TDRmn) is loaded into the TCRmn register by setting any channel start trigger bit (TSmn, TSHm1, TSHm3) of timer channel start register m (TSm) to "1".

The TCRmn register decrements the count while detecting the active edge of the Tlmn pin input. If TCRmn becomes "0000H", the value of TDRmn register is loaded again and INTTMmn is output.

After that, continue the same operation.

The output must be stopped by setting the TOEmn bit of the timer output enable register m (TOEm) to "0" because the TOmn pin outputs irregular waveforms based on external events.

The TDRmn register can be rewritten at any time, and the rewritten TDRmn register value is valid for the next cycle.

www.mcu.com.cn 150 / 624 Rev.1.0.3

# 5.8.3 Operation as frequency divider

The clock input from the TI00 pin can be divided and used as a divider for the output of the TO00 pin. The divided clock frequency of the TO00 output can be calculated using the following equation:

- Select rising or falling edge:
   Divider clock frequency = input clock frequency/ {(TDR00 set value+1) × 2}
- Select both edges:
   Divider clock frequency≈input clock frequency/ (TDR00 set value+1)

In the interval timer mode, the timer count register 00 (TCR00) is used as a decrement counter.

After setting the channel start trigger bit (TS00) of timer channel start register 0 (TS0) to "1", the value of timer data register 00 (TDR00) is loaded into the TCR00 register by detecting an active edge of Tl00. At this time, if the MD000 bit of Timer Mode Register 00 (TMR00) is "0", INTTM00 is not output and TO00 is not output alternately; if the MD000 bit of TMR00 register is "1", INTTM00 is output and TO00 is not output alternately. If the MD000 bit of TMR00 register is "1", INTTM00 is output and TO00 is output alternately.

The TCR00 register then counts down through the active edge of the TI00 pin input. If TCR00 changes to "0000H", TO00 performs an alternate output. At the same time, the value of the TDR00 register is loaded into the TCR00 register and counting continues.

If double edge detection is selected for the TI00 pin input, the duty cycle error of the input clock affects the clock period of the TO00 output's division.

The clock period of the TO00 output contains the sampling error of 1 run clock cycle.

clock period of the TOmn output = supposed TOmn output clock period ± operating clock period (error)

The TDRmn register can be rewritten at any time, and the rewritten TDRmn register value is valid for the next cycle.

# 5.8.4 Operation as input pulse interval measurement

The count value can be captured at the active edge of Tlmn and the interval between Tlmn input pulses can be measured. The software operation (TSmn=1) can also be set to capture the count value during the period when the TEmn bit is "1".

The pulse interval can be calculated using the following equation:

Tlmn input pulse interval = period of counting clock  $\times$  ((10000H  $\times$  TSRmn: OVF) + (TDRmn captured value +1))

In capture mode, the timer count register mn (TCRmn) is used as an increment counter.

If the channel start trigger bit (TSmn) of the timer channel start register m (TSm) is set to "1", the TCRmn register is incrementally counted from "0000H" by the count clock.

If the active edge of the TImn pin input is detected, the count value of TCRmn register is transferred (captured) to Timer Data Register mn (TDRmn), and the TCRmn register is cleared to "0000H", and then INTTMmn is output. If the counter overflows, the OVF bit of Timer Status Register mn (TSRmn) is set to "1". If the counter does not overflow, the OVF bit is cleared. After that, continue the same operation.

While capturing the count value to the TDRmn register, the OVF bit of the TSRmn register is updated according to whether or not overflow occurs during the measurement, and the overflow status of the captured value can be confirmed.

Even if the counter counts 2 or more complete cycles, the overflow is considered to have occurred and the OVF bit of the TSRmn register is set to "1". However, when two or more overflows occur, the interval value cannot be measured normally by the OVF bit.

Set the STSmn2~STSmn0 bit of the TMRmn register to "001B", and use the valid edge of Tlmn for start trigger and capture trigger.

# 5.8.5 Operation as input signal high-/low-level width measurement

The signal width (high-/low-level width) of Tlmn can be measured by starting counting at one edge of the input to the Tlmn pin and capturing the count value at the other edge. The Tlmn signal width of the Tlmn output can be calculated using the following equation:

Signal width of Tlmn input = period of count clock  $\times$  ((10000H  $\times$  TSRmn: OVF) + (TDRmn captured value +1))

In the Capture & Single Count mode, the timer count register mn (TCRmn) is used as an increment counter. If the channel start trigger bit (TSmn) of the timer channel start register m(TSm) is set to "1", the TEmn bit becomes "1", and the start edge detection wait state of the Tlmn pin is entered.

If the start edge of the TImn pin input (rising edge of the TImn pin input at the time of high-level width measurement) is detected, it is synchronized with the count clock and counts incrementally from "0000H". Then, if an active capture edge is detected (falling edge of TImn pin input at the time of high-level width measurement), the count value is transferred to the Timer Data Register mn (TDRmn) and INTTMmn is output at the same time. If the counter overflows, the OVF bit of the Timer Status Register mn (TSRmn) is set to "1". If the counter does not overflow, the OVF bit is cleared. The value of the TCRmn register changes to "Value passed to TDRmn register +1", and the start edge detection wait state of the TImn pin is entered. After that, continue the same operation.

While capturing the count value to the TDRmn register, the OVF bit of the TSRmn register is updated according to whether or not overflow occurs during the measurement, and the overflow status of the captured value can be confirmed.

Even if the counter counts 2 or more complete cycles, the overflow is considered to have occurred and the OVF bit of the TSRmn register is set to "1". However, when two or more overflows occur, the interval value cannot be measured normally by the OVF bit.

The CISmn1 and CISmn0 bits of the TMRmn register can be used to set whether the high-level width or low-level width of the TImn pin is to be measured. This function is designed to measure the input signal width of the TImn pin, so the TSmn bit cannot be set to "1" during the period when the TEmn bit is "1".

CISmn1, CISmn0=10B of the TMRmn register: Measures the low-level width.

CISmn1, CISmn0=11B of the TMRmn register: Measures the high-level width.

#### Notice:

- 1. When used as a LIN-bus support function, bit1 (ISC1) of the Input Switching Control Register (ISC) must be set to "1" and RxD0 should be used instead of TImn in the following description.
- 2. Because the Tlmn pin inputs are sampled by the operation clock selected by the CKSmn bit of the Timer Mode Registermn (TMRmn), an error of 1 operation clock is generated.

# 5.8.6 Operation as delay counter

The count can be decremented by the active edge detection (external event) of the TImn pin input and INTTTMmn (timer interrupt) is generated at any set interval.

During the period when the TEmn bit is "1", the TSmn bit can be set to "1" by software to start decreasing counting and generate INTTMmn (timer interrupt) at any set interval.

The interrupt generation period can be calculated using the following equation:

INTTMmn (timer interrupt) generation period = counting clock period × (TDRmn set value +1)

In the single count mode, the timer count register mn (TCRmn) is used as a decrement counter.

If the channel start trigger bit (TSmn, TSHm1, TSHm3) of the timer channel start register m(TSm) is set to "1", the TEmn bit, TEHm1 bit, TEHm3 bit become "1", and the active edge detection wait state of the Tlmn pin is entered. An active edge detection via the Tlmn pin input starts the TCRmn register and loads the value of the Timer Data Register mn (TDRmn). The TCRmn register counts decreasingly from the value of the loaded TDRmn register by counting the clock. If TCRmn becomes "0000H", INTTMmn is output and counting is stopped until the next active edge of the Tlmn pin input is detected.

The TDRmn register can be rewritten at any time, and the rewritten TDRmn register value is valid from the next cycle.

# 5.9 Multi-channel linkage operation function for general purpose timer unit

# 5.9.1 Operation as single trigger pulse output function

Using the 2 channels in pairs, a single trigger pulse with any delay pulse width can be generated from the input of the Tlmn pin. The delay and pulse width can be calculated using the following equation:

Delay = {TDRmn (master) set value +2} × counting clock period
Pulse width = {TDRmp (slave) set value} × counting clock period

In single count mode, the master channel operates and counts the delay. By detecting a start trigger, the timer count register mn (TCRmn) of the master channel starts to operate and loads the value of timer data register mn (TDRmn). The TCRmn register counts decreasingly from the value of the loaded TDRmn register by counting the clock. If TCRmn becomes "0000H", INTTMmn is output and counting stops before the next start trigger is detected.

In single count mode, the slave channel operates and counts the pulse width. The INTTMmn of the master channel is used as the start trigger and the TCRmp register of the slave channel is started and loaded with the value of the TDRmp register. The TCRmp register counts decreasingly from the value of the loaded TDRmp register by counting the clock. If the count value becomes "0000H", INTTMmp is output and counting is stopped until the next start trigger (INTTMmn of the master channel) is detected. The output level of TOmp becomes valid after INTTMmn has been generated from the master channel and after 1 count clock, if TCRmp becomes "0000H", it becomes invalid.

The software operation (TSmn=1) can also be used as a start trigger to output a single trigger pulse without using the Tlmn pin input.

Notice: Because the TDRmn register of the master channel and the TDRmp register of the slave channel have different loading timings, if the TDRmn register and the TDRmp register are rewritten during counting, they may compete with the loading timings and output an abnormal waveform. The TDRmn register must be rewritten after generating INTTMmn and the TDRmp register must be rewritten after generating INTTMmp.

# 5.9.2 Operation as PWM function

By using the 2 channels in pairs, pulses of any period and duty cycle can be generated. The period and duty cycle of the output pulses can be calculated using the following equations:

Pulse period = {TDRmn (master) set value +1} × counting clock period

Duty cycle [%] = {TDRmp (slave) set value} / {TDRmn (master) set value +1} ×100

0% output: TDRmp (slave) set value = 0000H

100% output: TDRmp (slave) set value ≥ {TDRmn (master) set value +1}

The master channel is used as the interval timer mode. If the channel start trigger bit (TSmn) of the timer channel start register m (TSm) is set to "1", an interrupt (INTTMmn) is output, and then the set value of the timer data register mn (TDRmn) is loaded into the timer count register mn (TCRmn), and the count is decremented by the count clock. When the count reaches "0000H", the value of the TDRmn register is loaded into the TCRmn register again after the INTTMmn is output, and the count is decremented. Thereafter, this operation is repeated before setting the channel stop trigger bit (TTmn) of the timer channel stop register m (TTm) to "1".

When used as PWM function, the master channel decrements the count and the period until "0000H" is counted as the PWM output (TOmp) period. The slave channel is used in single count mode. The value of TDRmp register is loaded into TCRmp register with INTTMmn of the master channel as the start trigger, and the count is decremented until "0000H". When the count reaches "0000H", INTTMmp is output and the next start trigger (INTTMmn of the master channel) is waited.

When used as PWM function, the slave channel decrements the count and the duty cycle of the PWM output (TOmp) for the period until "0000H" is counted.

After INTTMmn is generated from the master channel and 1 clock has elapsed, the PWM output (TOmp) becomes active and it becomes invalid when the value of TCRmp register of the slave channel is "0000H".

#### Notice:

- 1. When the set value of TDRmp (slave) > {Set value of TDRmn (master) +1}, the duty cycle exceeds 100% but is 100% output.
- 2. To rewrite both timer data register mn (TDRmn) of the master channel and the TDRmp register of the slave channel, a write access is necessary two times. The timing at which the values of the TDRmn and TDRmp registers are loaded to the TCRmn and TCRmp registers is upon occurrence of INTTMmn of the master channel. Thus, when rewriting is performed split before and after occurrence of INTTMmn of the master channel, the TOmp pin cannot output the expected waveform. To rewrite both the TDRmn register of the master and the TDRmp register of the slave, therefore, be sure to rewrite both the registers immediately after INTTMmn is generated from the master channel.

# 5.9.3 Operation as multiple PWM output function

This is a function that extends the PWM function and uses multiple slave channels for multiple PWM outputs with different duty cycles. For example, when using 2 slave channels in pairs, the period and duty cycle of the output pulse can be calculated by using the following equation:

```
Pulse period= {TDRmn(master) set value +1} × count clock period

Duty cycle1[%] = {TDRmp (slave 1) set value} / {TDRmn (master) set value+1} ×100

Duty cycle2[%] = {TDRmq (slave 2) set value} / {TDRmn(master) set value +1} ×100
```

In interval timer mode, the timer count register mn (TCRmn) of the master channel operates and counts the period. In single count mode, the TCRmp register of slave channel 1 operates and counts the duty cycle and outputs the PWM waveform from the TOmp pin. The TCRmp register loads the value of timer data register mp (TDRmp), using INTTMmn of the master channel as a start trigger, and starts counting down. When TCRmp = "0000H", the TCRmp outputs INTTMmp and stops counting until the next start trigger (INTTMmn of the master channel) has been input. The output level of TOmp becomes valid after INTTMmn has been generated from the master channel and after 1 count clock, if TCRmp becomes "0000H", it becomes invalid.

In the same way as the TCRmp register of the slave channel 1, the TCRmq register of the slave channel 2 operates in single count mode, counts the duty cycle, and outputs a PWM waveform from the TOmq pin. The TCRmq register loads the value of the TDRmq register, using INTTMmn of the master channel as a start trigger, and starts counting down. When TCRmq = "0000H", the TCRmq register outputs INTTMmq and stops counting until the next start trigger (INTTMmn of the master channel) has been input. The output level of the TOmq becomes active one count clock after generation of INTTMmn from the master channel, and inactive when TCRmq = 0000H.

When channel 0 is used as the master channel as above, up to 3 types of PWM signals can be output at the same time.

# Notice:

- 1. When the set value of TDRmp (slave 1) > {the set value of TDRmn (master) + 1} or {the set value of TDRmq (slave 2)} > {the set value of TDRmn (master) + 1}, the duty cycle exceeds 100%, but is 100% output.
- 2. To rewrite the timer data register mn (TDRmn) of the master channel and the TDRmp register of the slave channel 1 at the same time, at least 2 write accesses are required. Because the values of TDRmn register and TDRmp register are loaded into the TCRmn register and TCRmp register when the master channel generates INTTMmn, the TOmp pin cannot output the expected waveform if rewriting is performed before and after the master channel generates INTTMmn respectively. Therefore, to rewrite both the master TDRmn register and the slave TDRmp register, these two registers must be rewritten immediately after the master channel generates INTTMmn (the same applies to the TDRmq register of slave channel 2).

The TOmp and TOmq remains unchanged because the channel is in the stop state.  The TOmp pin and TOmq pin output the levels set by the TOmp and TOmq. |

www.mcu.com.cn 184 / 624 Rev.1.0.3

Table 5-32: Procedure for the multiple PWM output function (output two types of PWMs) (2/2)

|                      | Tocedure for the multiple i will output function  |   |
|----------------------|---|---|
|                      | Software operation  | Hardware status   |
| Start operation      | (Sets the TOEmp and TOEmq (slave) bits to 1 only when resuming operation.) The TSmn bit (master), and TSmp and TSmq (slave) bits of timer channel start register m (TSm) are set to 1 at the same time. The TSmn, TSmp, and TSmq bits automatically return to 0 because they are trigger bits.  | TEmn = 1, TEmp, TEmq = 1 When the master channel starts counting, INTTMmn is generated. Triggered by this interrupt, the slave channel also starts counting.  |
| Restart In operation | Set values of the TMRmn, TMRmp, TMRmq registers, TOMmn, TOMmp, TOMmq, TOLmn, TOLmp, and TOLmq bits cannot be changed.  Set values of the TDRmn, TDRmp, and TDRmq registers can be changed after INTTMmn of the master channel is generated.  The TCRmn, TCRmp, and TCRmq registers can always be read.  The TSRmn, TSRmp, and TSR0q registers are not used. | The counter of the master channel loads the TDRmn register value to timer count register mn (TCRmn) and counts down. When the count value reaches TCRmn = 0000H, INTTMmn output is generated. At the same time, the value of the TDRmn register is loaded to the TCRmn register, and the counter starts counting down again.  At the slave channel 1, the values of the TDRmp register are transferred to the TCRmp register, triggered by INTTMmn of the master channel, and the counter starts counting down. The output levels of TOmp become active one count clock after generation of the INTTMmn output from the master channel. It becomes inactive when TCRmp = 0000H, and the counting operation is stopped. At the slave channel 2, the values of the TDRmq register are transferred to TCRmq register, triggered by INTTMmn of the master channel, and the counter starts counting down. The output levels of TOmq become active one count clock after generation of the INTTMmn output from the master channel. It becomes inactive when TCRmq = 0000H, and the counting operation is stopped.  After that, the above operation is repeated. |
| Stop<br>operation    | The TTmn bit (master), TTmp, and TTmq (slave) bits are set to 1 at the same time.  The TTmn, TTmp, and TTmq bits automatically return to 0 because they are trigger bits.   | TEmn, TEmp, TEmq = 0, and count operation stops. The TCRmn, TCRmp, and TCRmq registers hold count value and stop. The TOmp and TOmq output are not initialized but hold current status.   |
|                      | The TOEmp and TOEmq bits of slave channels are  | The TOmp and TOmq pins output the TOmp and TOmq   |
| Timer4 stop          | Cleared to 0 and value is set to the TOmp and TOmq bits?  To hold the TOmp and TOmq pin output levels Clears the TOmp and TOmq bits to 0 after the value to be held is set to the port register.  When holding the TOmp and TOmq pin output levels are not necessary: Setting not required  The TM4mEN bit of the PER0 register is cleared to 0.            | The TOmp and TOmq pin output levels are held by port function.  The input clock of timer unit m is in the stop-providing state. Initialize all circuits and the SFR for each channel. (TOmp bit and TOmq bit become "0" and TOmp pin and TOmg pin become port function)   |

Remark: m: unit number (m= 0, 1) n: master channel number (n=0)

p: slave channel number q: slave channel number n \leqslant 3 (p and q are integers greater than n)

# **Chapter 6 EPWM Output Control Circuit**

Using the PWM output function of Timer, one DC motor or two stepper motors can be controlled. The output can be truncated by truncating the INTP0 input, and the EVENTC event. The software allows you to select from four outputs: Hi-Z output, low output, high output, and anti-truncation output during forced truncation.

## 6.1 Structure of output control circuit

The EPWM output control circuit consists of the following hardware.

Table 6-1: Structure of EPWM output control circuit

| Item             | Structure   |  |  |  |
|------------------|---|--|--|--|
|                  | EPWM input source selection register (EPWMSRC).           |  |  |  |
|                  | EPWM output control register (EPWMCTL).                   |  |  |  |
| Control register | EPWM force truncated input selection register (EPWMSTC).  |  |  |  |
| Control register | EPWM force truncated output selection register (EPWMSTL). |  |  |  |
|                  | EPWM status register (EPWMSTR).                           |  |  |  |
|                  | EPWM deadband control register (EPWMDTC)                  |  |  |  |
| Output           | EPWM output (EPWMO00~EPWMOP07)                            |  |  |  |

The block diagram of the EPWM output control circuit is shown in Figure 6-1.

Figure 6-1: Block diagram of the EPWM output control circuit

www.mcu.com.cn 186 / 624 Rev.1.0.3

## 6.2 Registers for controlling EPWM output control circuit

The real-time output control circuit is controlled by the following registers.

- Peripheral enable register 0 (PER1)
- EPWM input source select register (EPWMSRC)
- EPWM output control register (EPWMCTL)
- EPWM force truncated input select register (EPWMSTC)
- EPWM force truncated output select register (EPWMSTL)
- EPWM status register (EPWMSTR)
- EPWM deadband control register (EPWMDTC)
- Port mode register (PMxx)
- Port mode control register (PMCxx)
- Port register (Pxx)

#### 6.2.1 Peripheral enable register 1 (PER1)

The PER1 register is a register that sets the clock that enables or disables clocking each peripheral hardware.

Reduce power consumption and noise by stopping clocking unused hardware.

To use the EPWM function, EPWMEN must be set to "1".

See "4.3.6 peripheral enable registers 0, 1 (PER0, PER1)" for details.

#### 6.2.2 EPWM input source select register (EPWMSRC)

The EPWMSRC register selects the source clock of the input clock of the real-time output circuit. Select Timer's timer output TO01 or TO03 as the source clock and input to the EPWM.

The EPWMSRC register is set via an 8-bit memory operation command.

By generating a reset signal, the value of this register becomes "00H".

Table 6-2: Format of EPWM input source select register

| Address: 0x400 | 44400 |       | After reset: 0 | 0H    | R/W   |       |       |       |
|----------------|-------|-------|----------------|-------|-------|-------|-------|-------|
| Symbol         | 7     | 6     | 5              | 4     | 3     | 2     | 1     | 0     |
| EPWMSRC        | SRC07 | SRC06 | SRC05          | SRC04 | SRC03 | SRC02 | SRC01 | SRC00 |

| SRC0n | Selection of source clock for EPWM0n outputs |
|-------|--|
| 0     | Selects TO01                                 |
| 1     | Selects TO03                                 |

Remark: n: channel number (n=0~7)

#### 6.2.3 EPWM force truncated input select register (EPWMSTC)

EPWMSTC register is to select forces truncation of the input source.

The EPWMSTC register is set by an 8-bit memory manipulation instruction.

After a reset signal is generated, the value of this register changes to "00H".

Table 6-3: Format of EPWM force truncated input select register (EPWMSTC)

| Address: 0x40  | 044404 |   | After reset: 0 | 0H      | R/W    |       | ,       | ,       |
|----------------|--------|---|----------------|---------|--------|-------|---------|---------|
| Symbol         | 7      | 6 | 5              | 4       | 3      | 2     | 1       | 0       |
| <b>EPWMSTC</b> | 0      | 0 | 0              | REL_SEL | HS_SEL | IN_EG | SC_SEL1 | SC_SEL0 |

| SC_SEL1 | SC_SEL0 | Selection of truncation sources Note1,3,4 |

| 0       | 0       | Do not select                             |
| 0       | 1       | Do not select                             |
| 1       | 0       | INTP0 terminal input                      |
| 1       | 1       | Event input from EVENTC                   |

| IN_EG | Source of force truncation/edge selection of force truncation output source Note 1,2 |  |  |  |  |  |
|-------|--|--|--|--|--|--|
| 0     | Rising edge: Output force truncation Falling edge: Output force truncation released  |  |  |  |  |  |
| 1     | Rising edge: Output force truncation released Falling edge: Output force truncation  |  |  |  |  |  |

| HS_SEL | Output mode selection for forced truncation |
|--------|---|
| 0      | Software release                            |
| 1      | Hardware release                            |

| REL_SEL | Release timing selection for forced output truncation   |
|---------|---|
| 0       | After the release signal generated by hardware or software occurs, the truncation is immediately released and the pulse output is restored.   |
| 1       | After the release signal generated by hardware or software occurs, wait for the following timing: Select TO01 as the channel of the source clock: Truncation is released on the rising edge of the next TO01, and the pulse output is restored. Select TO03 as the channel of the source clock: the cut-off is released on the rising edge of the next TO03 and the pulse output is restored. |

#### Notice:

- 1. Set SC\_SEL1 and SC\_SEL0 at least three clocks apart after IN\_EG is set.
- 2. Valid only when INTP0 input is selected.
- 3. When using EVENTC to release the truncation, software must be selected to release (HS\_SEL set to 1). There is no restriction when using INTP0 input.
- 4. The effective width of the input selected INTP0 must be greater than one clock cycle.

www.mcu.com.cn 188 / 624 Rev.1.0.3

## 6.2.4 EPWM output control register (EPWMCTL)

The EPWMCTL register enables control and reverse control of the waveform outputs of EPWMO00~EPWMO07.

The EPWMCTL register is set via a 16-bit memory manipulation instruction.

After the reset signal is generated, the value of this register becomes "00H".

Table 6-4: Format of EPWM output control register (EPWMCTL)

| Address: 0x40044408 |      |      | After | reset: 0 | H0000 | R/W  |      |      |      |      |      |      |      |      |      |      |
|---------------------|------|------|-------|----------|-------|------|------|------|------|------|------|------|------|------|------|------|

| 1    | Reversed                          |

Remark: n: channel number (n=0~7)

www.mcu.com.cn 189 / 624 Rev.1.0.3

#### 6.2.5 EPWM force truncated output select register (EPWMSTL)

The output state of the EPWMO terminal when the EPWMSTL register is forcibly truncated.

The EPWMSTL register is set via a 16-bit memory manipulation instruction.

After the reset signal is generated, the value of this register becomes "00H".

Table 6-5: Format of EPWM force truncated output select register (EPWMSTL)

| Address | AI   | 0000H |      | R/   | W    |      |      |      |      |      |      |      |      |      |      |      |
|---------|------|-------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|
| Symbol  | 15   | 14    | 13   | 12   | 11   | 10   | 9    | 8    | 7    | 6    | 5    | 4    | 3    | 2    | 1    | 0    |

| 0    | 0    | Truncation is prohibited                    |
| 0    | 1    | HI-Z output                                 |
| 1    | 0    | Low level output                            |
| 1    | 1    | High level output                           |

Remark: n: channel number (n=0~7)

## **6.2.6 EPWM status register (EPWMSTR)**

The EPWMSTR register clears the forced truncation signal and displays the truncation status. If the clear trigger bit HZCLR is set to "1", the truancy state is released. When the truncation status indicates that the signal of the SHTFLG is high, it enters the forced truncation state. Bit0 is write-only bit, and the read value is always "0". Bit7~1 is read-only.

The EPWMSTR register is set via an 8-bit memory manipulation instruction.

After the reset signal is generated, the value of this register becomes "00H".

Table 6-6: Format of EPWM status register (EPWMSTR)

| Address: 0x40044 | 110 | After reset: | 0000H | R/W |   |   |        |       |
|------------------|-----|--------------|-------|-----|---|---|--------|-------|
| Symbol           | 7   | 6            | 5     | 4   | 3 | 2 | 1      | 0     |
| EPWMSTR          | 0   | 0            | 0     | 0   | 0 | 0 | SHTFLG | HZCLR |

| SHTFLG | Force truncation status flag |
|--------|------------------------------|
| 0      | Normal output state          |
| 1      | Force truncation state       |

| HZCLR | Software release for forced signal truncation |
|-------|---|
| 0     | -   |
| 1     | Software release truncated status             |

Remark: If truncation is prohibited by setting the forced truncatd output selection register (EPWMSTL), no truncation is performed even though SHTFLG is set to "1" due to the occurrence of input from an external cutoff source.

www.mcu.com.cn 190 / 624 Rev.1.0.3

#### 6.2.7 EPWM deadband control register (EPWMDTC)

The EPWMDTC register enables the deadband of the waveform output from EPWMO00 to EPWMO07 and controls the deadband value.

The EPWMDTC register is set by a 16-bit memory manipulation instruction.

After a reset signal is generated, the value of this register changes to "00H".

Table 6-7: Format of EPWM deadband control register (EPWMDTC)

|             | : 0x40044414 |    |    | After reset: 0000H |          |    | R/W |   |      |      |      |      |      |     |     |     |  |
|-------------|--------------|----|----|--------------------|----------|----|-----|---|------|------|------|------|------|-----|-----|-----|--|
| Symbo<br>I  | 15           | 14 | 13 | 12                 | 11       | 10 | 9   | 8 | 7    | 6    | 5    | 4    | 3    | 2   | 1   | 0   |  |

| ENn | Deadband enable for EPWMO0n outputs |
|-----|-------------------------------------|
| 1   | Enables                             |
| 0   | Dsiables                            |

Remark: n: channel number (n=0~7)

#### 6.2.8 Control registers for port functions of EPWM output pins

When using the EPWM output, the control register (Port Mode Register (PMxx, PMCxx)) for the port function multiplexed with the EPWM output pin (EPWMOn pin) must be set. For details, refer to "2.3.1 Port Mode Register (PMxx)".

When using the multiplexed ports of the EPWM pins as outputs of EPWMO, the bits of the port mode registers (PMxx, PMCxx) corresponding to each port must be set to "0". In this case, the bit of the port register (Pxx) can be "0" or "1".

For details, refer to "Table 6-2 Pin Function Figures Map"

www.mcu.com.cn 191 / 624 Rev.1.0.3

## 6.3 Operation of EPWM output control circuit

#### 6.3.1 Initial setup

The timer waveform selects the TAU output (TO01, TO03) as the source clock through the EPWSRC register. The positive or inverting phase of the timer waveform can be fixed by setting the EPWMCTL register.

In the event of forced truncation, the Hi-Z output, low output, high output, or disable cut-off output can be selected through the setting of the EPWMSTL register.

Start Setting of Timer Start Setting of EPWMSRC register Setting of EPWMCTL register Setting of EPWMSTL register Setting of EPWMSTR register Setting of EPWMSTC register Setting of PORT control End

Figure 6-2: Initial configuration flow of registers

#### 6.3.2 Normal operation

Depending on the register settings, four output data can be selected, namely forward waveform output, inverted waveform output, low level output, and high-level output. The EPWMCTL registers can be changed at runtime. Both OE0n bits and IE0n bits must be written at the same time.

For details, please refer to "Table 6-8 Operation Instructions for truncation signals".

www.mcu.com.cn 193 / 624 Rev.1.0.3

#### 6.3.3 Force truncation processing

The EPWM can select INTP0, and EVENTC event by setting the bit1, 0 of the EPWMSTC register, causing the EPWMO output to enter a forced truncation state.

(1) Occurrence of forced truncation

The truncated state is entered via the INTP0 input, and the EVENTC event. By bit2(IN\_EG) of EPWMSTC register, it can select the rising or falling edge and enter the truncated state after 1 to 2 clocks. For details, please refer to Figure 6-4.

- (2) Release of forced truncation
  - a) Software release: When bit3 (HS\_SEL) of EPWMSTC register is 0, the software release mode is used. Bit0 (HZCLR) of EPWMSTR register is the clear bit of truncated status. When the truncated status flag SHTFLG is high, if the HZCLR bit is set to "1", the truncated status flag SHTFLG goes low and the forced truncated status is released.
  - b) Hardware release: When bit3 (HS\_SEL) of EPWMSTC register is 1, the hardware release mode is used. The forced truncation state is released by INTP0 input.

## 6.4.2 Control timing of three-phase brushless DC motors

Figure 6-6: Control timing of three-phase brushless DC motor

1 3 4 (5) 6 Hall a Hall b Hall c U+ W-

#### 6.4.3 Example of register setting

In this example, the EPWM source select register (EPWMSRC) and EPWM control register (EPWMCTL) are initialized to simultaneously output a waveform of positive rotation from EPWM00 ~ EPWM05 to the BLDC motor.

- 1. Set EPWMSRC5 to EPWMSRC0 in the EPWMSRC register to "0" and channel 1 of Timer as the input source of EPWMO00 ~ EPWMO05.
- 2. Set EPWMOE3 to EPWMOE0 in the EPWMCTL register to "1" to allow EPWMO03 ~ EPWM00 to be output. Set EPWMIE3 to EPWMIE0 of EPWMCTL register to "0", EPWMO00 ~ EPWMO03 will be output in positive direction.
- 3. Set EPWMOE5 to EPWMOE4 in the EPWMCTL register to "1" to allow EPWMO05 to EPWM04 to be output. Set EPWMIE5 ~ EPWMIE4 in the EPWMCTL register to "1" to reverse the output of EPWMO04~ EPWMO05.

Table 6-9: Example of setting EPWMCTL0 register

| Description   | Set value of the EPWMCTL |
|---|--------------------------|
| State ①: rising edge of Hall a Disable U+, U+ reverse outputs, enable V-, V-forward outputs.      | 0x0110                   |

www.mcu.com.cn 197 / 624 Rev.1.0.3

## 6.5 Example of stepper motor control

The following is an example of using eight real-time outputs to control two 2-phase stepper motors.

## 6.5.1 Example of a hardware connection

An example of a hardware connection to control two stepper motors is shown in Figure 6-7.

Figure 6-7: Example of a hardware connection

www.mcu.com.cn 198 / 624 Rev.1.0.3

#### 6.5.2 Control method

The stepper motor is rotated, reversed or stopped in two-phase excitation mode by using eight EPWMOs. Control the rotation speed via Timer's PWM mode.

In this example, Timer's CH0 and CH1 are used for the control of stepper motor 1, CH2 and CH3 are used for the control of stepper motor 2. If you combine 2 Timer channels, you can generate pulses of any period and duty cycle. CH0 and CH2 are the main control channels and operate as interval timer mode. CH1 and CH3 are slave channels and operate as single-count mode.

In addition, the cross-current prevention time (no overlapping time) is inserted when switching the output type.

An example of a waveform for stepper motor control is shown in Figure 6-8.

www.mcu.com.cn 199 / 624 Rev.1.0.3

# 6.5.3 Example of register setting

Table 6-10: Example of setting the register that controls the stepper motor

| Status |   | Set value of EPWMSRC | Set value of EPWMCTL |
|--------|---|----------------------|----------------------|
|        | 1 | 0x00                 | 0x4400               |

# **Chapter 7 Real-Time Clock**

#### 7.1 Function of real-time clock

The real-time clock has the following functions.

Holds counters for years, months, weeks, days, hours, minutes, and seconds up to a maximum of 99 years.

Fixed cycle break (cycles: 0.5 seconds, 1 second, 1 minute, 1 hour, 1 day, 1 month)

Alarm clock interrupt (alarm clock: week, hour, minute)

1Hz pin out capability

#### 7.2 Structure of real-time clock

The real-time clock consists of the following hardware.

Table 7-1: Structure of real-time clock

| Item             | Structure                                  |
|------------------|--|
| Counter          | Internal counter (16-bit)                  |
|                  | Peripheral enable register 0 (PER0)        |
|                  | Real-time clock selection register (RTCCL) |
|                  | Real-time clock control register 0 (RTCC0) |
|                  | Real-time clock control register 1 (RTCC1) |
|                  | Second count register (SEC)                |
|                  | Minute count register (MIN)                |
|                  | Hour count register (HOUR)                 |
| Control register | Day count register (DAY)                   |
|                  | Week count register (WEEK)                 |
|                  | Month count register (MONTH)               |
|                  | Year count register (YEAR)                 |
|                  | Clock error correction register (SUBCUD)   |
|                  | Alarm clock minute register (ALARMWM)      |
|                  | Alarm clock hour register (ALARMWH)        |
|                  | Alarm clock week register (ALARMWW)        |

Notice: The reset of the above RTC control registers are only controlled by the POR reset.

Figure 7-1: Block diagram of real-time clock

Notice: Count years, months, weeks, days, hours, minutes and seconds only if you select F<sub>mx</sub>/F<sub>hoco</sub> clock (≈32, 768KHZ after every week) or the secondary system clock (F<sub>SUB</sub>=32.768kHz) as the running clock for the real-time clock. When a low-speed internal oscillator clock (F<sub>IL</sub>=15kHz) is selected, only a fixed cycle interrupt function is used. The fixed cycle interrupt interval when selecting F<sub>IL</sub> is calculated using the following equation: Fixed period (value selected by the RTCC0 register) × F<sub>SUB</sub>/F<sub>IL</sub>.

www.mcu.com.cn 202 / 624 Rev.1.0.3

## 7.3 Registers for controlling real-time clock

The real-time clock is controlled through the following registers.

Peripheral enable register 0 (PER0).

Real-time clock selection register (RTCCL)

Real-time clock control register 0 (RTCC0)

Real-time clock control register 1 (RTCC1)

Second count register (SEC)

Minute count register (MIN)

Hour count register (HOUR)

Day count register (DAY)

Week count register (WEEK)

Month count register (MONTH)

Year count register (YEAR)

Clock error correction register (SUBCUD)

Alarm clock minute register (ALARMWM)

Alarm clock hour register (ALARMWH)

Alarm clock week register (ALARMWW)

Port mode register (PMxx)

Port mode control register (PMCxx)

Port multiplexing function configuration register (PxxCFG)

#### 7.3.1 Peripheral enable register 0 (PER0)

The PER0 register is a register that sets a clock that is allowed or prohibited to supply to each peripheral hardware. Reduce power consumption and noise by stopping clock supply to unused hardware.

You must set bit7 (RTCEN) to "1" when you want to use real-time clocks. The PER0 register is set by an 8-bit memory manipulation instruction. After the reset signal is generated, the value of this register changes to "00H".

Table 7-2: Format of peripheral enable register 0 (PER0)

| Address: 0x40020420 |       | After reset:<br>00H | R/W   |         |        |        |        |        |
|---------------------|-------|---------------------|-------|---------|--------|--------|--------|--------|
| Symbol              | 7     | 6                   | 5     | 4       | 3      | 2      | 1      | 0      |
| PER0                | RTCEN | 0                   | ADCEN | IICA0EN | SAU1EN | SAU0EN | TM41EN | TM40EN |

| RTCEN | Control of an input clock of a real-time clock (RTC) and a 15-bit interval timer       |
|-------|--|
|       | Stop to supply the input clock.  |
| 0     | You cannot write the SFR used by the real-time clock (RTC) and 15-bit interval timers. |
|       | The real-time clock (RTC) and the 15-bit interval timer are reset.                     |
|       | Supply the input clock.  |
| I     | SFRs that can read and write real-time clocks (RTCs) and 15-bit interval timers.       |

#### Notice:

1. If you want to use the real-time clock, you must first set the RTCEN bit to "1" while the counting clock (F<sub>RTC</sub>) oscillation is stable, and then set the following registers. When the RTCEN bit is "0", the write operation of the real-time clock control register is ignored, and the read values are initial (except RTCCL, port mode register, and port register).

Real-time clock control register 0 (RTCC0)

Real-time clock control register 1 (RTCC1)

Second count register (SEC)

Minute count register (MIN)

Hour count register (HOUR)

Day count register (DAY)

Week count register (WEEK)

Month count register (MONTH)

Year count register (YEAR)

Clock error correction register (SUBCUD)

Alarm clock minute register (ALARMWM)

Alarm clock hour register (ALARMWH)

Alarm clock week register (ALARMWW)

2. By setting the RTCLPC bit in the Subsystem Clock Supply Mode Control Register (OSMC) to "1", the subsystem clock can be stopped for peripheral functions other than the real-time clock and 15-bit interval timer in deep sleep mode or sleep mode running with the subsystem clock.

www.mcu.com.cn 204 / 624 Rev.1.0.3

## 7.3.2 Real-time clock selection register (RTCCL)

A real-time clock and a count clock of a 15-bit interval timer (F<sub>RTC</sub>) can be selected through RTCCL.

Table 7-3: Format of real-time clock selection register (RTCCL)

| 1       | 1       | 0      | 0      | Main clock F <sub>MAX</sub> /F <sub>HOCO</sub> (via RTCCL7 selection)/488              |
| 1       | 1       | 1      | 0      | Main clock F <sub>MAX</sub> /F <sub>HOCO</sub> (via RTCCL7 selection)/244              |

www.mcu.com.cn 205 / 624 Rev.1.0.3

#### 7.3.3 Real-time clock control register 0 (RTCC0)

This is an 8-bit register that sets the start or stop of real-time clock operation, the control of RTC1HZ pins, the 12/24-hour system and fixed cycle interrupts.

The RTCC0 register is set by an 8-bit memory manipulation instruction. After the reset signal is generated, the value of this register changes to "00H".

Table 7-4: Format of real-time clock control register 0 (RTCC0)

| Address | : 0x40044F5D | After reset:<br>00H | R/W                    |   |      |     |     |     |
|---------|--------------|---------------------|------------------------|---|------|-----|-----|-----|
| Symbol  | 7            | 6                   | 5                      | 4 | 3    | 2   | 1   | 0   |
| RTCC0   | RTCE         | 0                   | RCLOE1 <sup>Note</sup> | 0 | AMPM | CT2 | CT1 | CT0 |

| RTCE | Real-time clock operation control |
|------|-----------------------------------|
| 0    | Stop the counter running.         |
| 1    | Start the counter running.        |

| RCLOE1 | Output control of RTC1HZ pin      |
|--------|-----------------------------------|
| 0      | Disables RTC1HZ pin output (1Hz). |
| 1      | Enables RTC1HZ pin output (1Hz).  |

|   | AMPM | Selection of 12-hour system/24-hour system       |
|---|------|--|
|   | 0    | 12-hour system (indicates morning or afternoon). |
| ſ | 1    | 24-hour system                                   |

To change the value of the AMPM bit, the RWAIT bit (bit 0 of the Real Time Clock Control Register 1 (RTCC1)) must be set to "1" and then rewritten. If the value of the AMPM bit is changed, the value of the hour count register (HOUR) changes to the corresponding value of the set time system.

The time bits are represented as shown in Table 7-11

| CT2 | CT1 | CT0 | Selection of fixed cycle interrupt (INTRTC)                     |
|-----|-----|-----|---|
| 0   | 0   | 0   | The fixed-cycle interrupt function is not used.                 |
| 0   | 0   | 1   | Once every 0.5 seconds (synchronized with seconds accumulation) |
| 0   | 1   | 0   | Once every 1 second (synchronized with seconds accumulation)    |
| 0   | 1   | 1   | Once every minute (00 seconds per minute).                      |
| 1   | 0   | 0   | Once every hour (00 minutes and 00 seconds per hour).           |
| 1   | 0   | 1   | Once a day (00:00:00 per day).                                  |
| 1   | 1   | ×   | Once a month (1st of each month at 00:00:00 a.m.).              |

To change the value of bits CT2~CT0 while the counter is running (RTCE=1), you must do the rewrite after setting INTRTC to disable interrupt processing via the interrupt mask flag register, and you must clear the RIFG flag and RTCIF flag after the rewrite, and then set it to enable interrupt processing.

Note 1: When the RTCE bit is "1", the RCLOE1 bit cannot be changed.

Note 2: When the RTCE bit is "0", 1Hz is not output even if the RCLOE1 is set to "1".

Remark: x: Ignore

## 7.3.4 Real-time clock control register 1 (RTCC1)

This is an 8-bit register that controls the alarm clock interrupt function and counter wait. The RTCC1 register is set by an 8-bit memory manipulation instruction. After a reset signal is generated, the value of this register becomes "00H".

Table 7-5: Format of real-time clock control register 1 (RTCC1) (1/2)

| Address: 0x40044F5E |      | After reset:<br>00H | R/W |      |      |   |      |       |
|---------------------|------|---------------------|-----|------|------|---|------|-------|
| Symbol              | 7    | 6                   | 5   | 4    | 3    | 2 | 1    | 0     |
| RTCC1               | WALE | WALIE               | 0   | WAFG | RIFG | 0 | RWST | RWAIT |

| WALE | Operation control of the alarm clock |
|------|--------------------------------------|
| 0    | Consistent operation is invalid.     |
| 1    | Consistent operation is valid.       |

To set the WALE bit when the counter is running (RTCE=1) and the WALIE bit is "1", you must set INTRTC to disable interrupt processing through the interrupt mask flag register before the rewrite and clear the WAFG flag and RTCIF flag after the rewrite. To set each alarm register (WALIE flag of RTCC1 register, alarm minute register (ALARMWM), alarm hour register (ALARMWH) and the alarm week register (ALARMWW)), the WALE bit must be set to "0" (invalid for consistent operation).

| WALIE | Operation control of the alarm clock interrupt (INTRTC) function |
|-------|--|
| 0     | No consistent alarm interruptions.                               |
| 1     | Generate consistent alarm interruptions.                         |

|   | WAFG | Alarm clock detection status flag |
|---|------|-----------------------------------|
|   | 0    | The alarm clock is inconsistent.  |
| Ī | 1    | Consistent alarms detected.       |

This is a status flag that indicates that an alarm clock has been detected consistently. It is only valid when the WALE bit is "1" and changes to "1" after one FRTC clock has elapsed and the alarm is detected.

Clear this flag by writing "0" to it. Writing a "1" is not valid.

Table 7-6: Format of real-time clock control register 1 (RTCC1) (2/2)

| RIFG   | Fixed-cycle interrupt status flag           |  |  |
|--|---|--|--|
| 0  | No fixed-cycle interruptions are generated. |  |  |
| 1  | Generate fixed-cycle interrupts.            |  |  |
| This is a status flag that indicates a fixed-cycle interrupt. When a fixed-cycle interrupt is generated, this flag is "1". |   |  |  |

This is a status flag that indicates a fixed-cycle interrupt. When a fixed-cycle interrupt is generated, this flag is "1". Clear this flag by writing "0" to it. Writing a "1" is not valid.

| RWST | Wait status flag for the real-time clock  |
|------|---|
| 0    | The counter is running.                   |
| 1    | It is in read-write mode for the counter. |
|      |   |

This is the state that indicates whether the setting of the RWAIT bit is valid. The count value must be read and written after confirming that this flag is "1".

| RWAIT | Wait control of the real-time clock  |
|-------|--|
| 0     | Set to counter run.  |
| 1     | Set the SEC to YEAR counter to stop running and enter the read/write mode of the counter |

This bit controls the operation of the counter. To read and write a count value, you must write "1" to this bit.

Because the internal counter (16-bit) continues to run, the read and write must end within 1 second and then return to "0".

The time required from the RWAIT bit set to "1" to the time the count value can be read and written (RWST=1) is up to 1 FRTC clock.

If an internal counter (16 bits) overflows when the RWAIT bit is "1", the overflow state is maintained and the count is incremented after the RWAIT bit becomes "0".

However, when the second count register is written, the overflow state that occurs is not maintained.

#### Notice:

- Fixed-cycle interrupts and alarm-consistent interrupts use the same interrupt source (INTRTC).
   In the case of using these two interrupts at the same time, when INTRTC occurs, you can determine which interrupt occurred by acknowledging the fixed-cycle interrupt status flag (RIFG) and the alarm detection status flag (WAFG).
- 2. If writing to the second count register (SEC), then clear the internal counter (16-bit).

www.mcu.com.cn 208 / 624 Rev.1.0.3

## 7.3.5 Clock error correction register (SUBCUD)

This is a register that can correct the clock speed with high accuracy by changing the overflow value (reference value: 7FFFH) from the internal counter (16 bits) to the second count register (SEC).

The SUBCUD register is set by a 16-bit memory manipulation instruction. After a reset signal is generated, the value of this register becomes "0000H".

Table 7-7: Format of clock error correction register (SUBCUD)

| Address: 0x40044F34H |     | After reset:<br>0000H | R/W |     | o o | `   | ,  |    |
|----------------------|-----|-----------------------|-----|-----|-----|-----|----|----|
| Symbol               | 15  | 14                    | 13  | 12  | 11  | 10  | 9  | 8  |
| SUBCUD               | DEV | 0                     | 0   | F12 | F11 | F10 | F9 | F8 |
|                      | 7   | 6                     | 5   | 4   | 3   | 2   | 1  | 0  |
|                      | F7  | F6                    | F5  | F4  | F3  | F2  | F1 | F0 |

| DEV   | Setting of clock error correction timings  |
|---|--|
| 0   | Corrects clock error when the second digits are at 00, 20, or 40 (every 20 seconds). |
| 1   | Corrects clock error only when the second digits are at 00 (every 60 seconds).       |
| Writing to the SUBCUD register at the following timing is prohibited. |  |
| When DEV = 0 is set: For a period of SEC = 00H, 20H, 40H              |  |
| When DEV =  | 1 is set: For a period of SEC = 00H  |

| F12             | Setting of clcok error correction value  |
|-----------------|--|
| 0               | Increases by {(F11,F10,F9,F8,F7,F6,F5,F4,F3,F2,F1,F0)-1}×2                         |
| 1               | Decreases by {(/ F11,/ F10,/ F9,/ F8,/ F7,/ F6,/ F5,/ F4,/ F3,/ F2,/ F1,/ F0)+1}×2 |
| (1,0,0,0,0,0,0, | F9,F8,F7,F6,F5,F4,F3,F2,F1,F0)=(0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,0,             |
|                 |  |

Remark: "/" indicates the inverted value of each bit.

The range of value that can be corrected by using the clock error correction register (SUBCUD) is shown below.

|  | DEV = 0 (correction every 20 seconds) | DEV = 1 (correction every 60 seconds) |
|--|---------------------------------------|---------------------------------------|
| Correctable range                      | -12496.9ppm~12496.9ppm                | -4165.6ppmto4165.6ppm                 |
| Maximum excludes<br>quantization error | ±1.53ppm                              | ±0.51ppm                              |
| Minimum resolution                     | ±3.05ppm                              | ±1.02ppm                              |

Notice: If a correctable range is -4165.6 ppm or lower and 4165.6 ppm or higher, set 0 to DEV.

#### 7.3.6 Second count register (SEC)

The SEC register is an 8-bit register that takes a value of 0 to 59 (decimal) and indicates the count value of seconds. It counts up when the internal counter (16-bit) overflows.

When data is written to this register, it is written to a buffer and then to the counter up to two cycles of F<sub>RTC</sub> later. Set a decimal value of 00 to 59 to this register in BCD code.

The SEC register is set by an 8-bit memory manipulation instruction. After a reset signal is generated, the value of this register becomes "00H".

Table 7-8: Format of second count register (SEC)

| Address: 0x40044F52 |   | After reset:<br>00H | R/W   |       |      |      |      |      |
|---------------------|---|---------------------|-------|-------|------|------|------|------|
| Symbol              | 7 | 6                   | 5     | 4     | 3    | 2    | 1    | 0    |
| SEC                 | 0 | SEC40               | SEC20 | SEC10 | SEC8 | SEC4 | SEC2 | SEC1 |

#### Notice:

- 1. When it reads or writes from/to the register while the counter is in operation (RTCE = 1), follow the procedures described in "7.4.3 Reading/writing real-time clock".
- 2. The internal counter (16-bit) is cleared when the second count register (SEC) is written.

## 7.3.7 Minute count register (MIN)

The MIN register is an 8-bit register that takes a value of 0 to 59 (decimal) and indicates the count value of minutes. It counts up when the second counter overflows.

When data is written to this register, it is written to a buffer and then to the counter up to two cycles of  $F_{RTC}$  later. Even if the second count register overflows while this register is being written, this register ignores the overflow and is set to the value written. Set a decimal value of 00 to 59 to this register in BCD code.

The MIN register is set by an 8-bit memory manipulation instruction. After a reset signal is generated, the value of this register becomes "00H".

Table 7-9: Format of minute count register (MIN)

| Address | : 0x40044F53 | After reset:<br>00H | R/W   |       |      |      |      |      |
|---------|--------------|---------------------|-------|-------|------|------|------|------|
| Symbol  | 7            | 6                   | 5     | 4     | 3    | 2    | 1    | 0    |
| MIN     | 0            | MIN40               | MIN20 | MIN10 | MIN8 | MIN4 | MIN2 | MIN1 |

Notice: When it reads or writes from/to the register while the counter is in operation (RTCE = 1), follow the procedures described in "7.4.3 Reading/writing real-time clock".

#### 7.3.8 Hour count register (HOUR)

The HOUR register is an 8-bit register that takes a value of 00 to 23 or 01 to 12 and 21 to 32 (decimal) and indicates the count value of hours. It counts up when the minute counter overflows.

When data is written to this register, it is written to a buffer and then to the counter up to two cycles of F<sub>RTC</sub> later. Even if the minute count register overflows while this register is being written, this register ignores the overflow and is set to the value written.

Specify a decimal value of 00 to 23, 01 to 12, or 21 to 32 by using BCD code according to the time system specified using bit 3 (AMPM) of real-time clock control register 0 (RTCC0).

If the AMPM bit value is changed, the values of the HOUR register change according to the specified time system. The HOUR register is set by an 8-bit memory manipulation instruction. After a reset signal is generated, the value of this register becomes "12H".

However, the value of this register is 00H if the AMPM bit is set to 1 after reset.

Table 7-10: Format of hour count register (HOUR)

| Address | : 0x40044F54 | After reset:<br>12H | R/W    |        |       |       |       |       |
|---------|--------------|---------------------|--------|--------|-------|-------|-------|-------|
| Symbol  | 7            | 6                   | 5      | 4      | 3     | 2     | 1     | 0     |
| HOUR    | 0            | 0                   | HOUR20 | HOUR10 | HOUR8 | HOUR4 | HOUR2 | HOUR1 |

#### Notice:

- Bit 5 (HOUR20) of the HOUR register indicates AM(0)/PM(1) if AMPM = 0 (if the 12-hour system is selected).
- 2. When it reads or writes from/to the register while the counter is in operation (RTCE = 1), follow the procedures described in "7.4.3 Reading/writing real-time clock".

Table 7-11 shows the relationship between the setting value of the AMPM bit, the hour count register (HOUR) value, and time.

Table 7-11: Displayed time digits

| 24-Hour Dis | splay (AMPM = 1) | 12-Hour Dis | play (AMPM = 0) |
|-------------|------------------|-------------|-----------------|
| Time        | HOUR Register    | Time        | HOUR Register   |
| 0           | 00H              | 12 a.m.     | 12H             |
| 1           | 01H              | 1 a.m.      | 01H             |
| 2           | 02H              | 2 a.m.      | 02H             |
| 3           | 03H              | 3 a.m.      | 03H             |
| 4           | 04H              | 4 a.m.      | 04H             |
| 5           | 05H              | 5 a.m.      | 05H             |
| 6           | 06H              | 6 a.m.      | 06H             |
| 7           | 07H              | 7 a.m.      | 07H             |
| 8           | 08H              | 8 a.m.      | 08H             |
| 9           | 09H              | 9 a.m.      | 09H             |
| 10          | 10H              | 10 a.m.     | 10H             |
| 11          | 11H              | 11 a.m.     | 11H             |
| 12          | 12H              | 12 p.m.     | 32H             |
| 13          | 13H              | 1 p.m.      | 21H             |
| 14          | 14H              | 2 p.m.      | 22H             |
| 15          | 15H              | 3 p.m.      | 23H             |
| 16          | 16H              | 4 p.m.      | 24H             |
| 17          | 17H              | 5 p.m.      | 25H             |
| 18          | 18H              | 6 p.m.      | 26H             |
| 19          | 19H              | 7 p.m.      | 27H             |
| 20          | 20H              | 8 p.m.      | 28H             |
| 21          | 21H              | 9 p.m.      | 29H             |
| 22          | 22H              | 10 p.m.     | 30H             |
| 23          | 23H              | 11 p.m.     | 31H             |

The HOUR register value is set to 12-hour display when the AMPM bit is "0" and to 24-hour display when the AMPM bit is "1". In 12-hour display, the fifth bit of the HOUR register indicates AM/PM. 0 for AM and 1 for PM.

www.mcu.com.cn 212 / 624 Rev.1.0.3

#### 7.3.9 Day count register (DAY)

The DAY register is an 8-bit register that takes a value of 1 to 31 (decimal) and indicates the count value of days. It counts up when the hour counter overflows. This counter counts as follows:

01 to 31 (January, March, May, July, August, October, December)

01 to 30 (April, June, September, November)

01 to 29 (February, leap year)

01 to 28 (February, normal year)

When data is written to this register, it is written to a buffer and then to the counter up to two cycles of  $F_{RTC}$  later. Even if the hour count register overflows while this register is being written, this register ignores the overflow and is set to the value written. Set a decimal value of 01 to 31 to this register in BCD code.

The DAY register is set by an 8-bit memory manipulation instruction. After a reset signal is generated, the value of this register becomes "01H".

Table 7-12: Format of day count register (DAY)

| Address: | 0x40044F56H | After reset:<br>01H | R/W   |       |      |      |      |      |
|----------|-------------|---------------------|-------|-------|------|------|------|------|
| Symbol   | 7           | 6                   | 5     | 4     | 3    | 2    | 1    | 0    |
| DAY      | 0           | 0                   | DAY20 | DAY10 | DAY8 | DAY4 | DAY2 | DAY1 |

Notice: When it reads or writes from/to the register while the counter is in operation (RTCE = 1), follow the procedures described in "7.4.3 Reading/writing real-time clock".

#### 7.3.10 Week count register (WEEK)

The WEEK register is an 8-bit register that takes a value of 0 to 6 (decimal) and indicates the count value of weekdays. It counts up in synchronization with the day counter.

When data is written to this register, it is written to a buffer and then to the counter up to two cycles of  $F_{RTC}$  later. Set a decimal value of 00 to 06 to this register in BCD code.

The WEEK register is set by an 8-bit memory manipulation instruction. After a reset signal is generated, the value of this register becomes "00H".

Table 7-13: Format of week count register (WEEK)

| Address: 0x40044F55H |   | After reset:<br>00H | R/W |   |   |       |       |       |
|----------------------|---|---------------------|-----|---|---|-------|-------|-------|
| Symbol               | 7 | 6                   | 5   | 4 | 3 | 2     | 1     | 0     |
| WEEK                 | 0 | 0                   | 0   | 0 | 0 | WEEK4 | WEEK2 | WEEK1 |

Notice: The value corresponding to the month count register (MONTH) or the day count register (DAY) is not stored in the week count register (WEEK) automatically. After reset release, set the week count register as follow:

| Day       | WEEK |
|-----------|------|
| Sunday    | 00H  |
| Monday    | 01H  |
| Tuesday   | 02H  |
| Wednesday | 03H  |
| Thursday  | 04H  |
| Friday    | 05H  |
| Saturday  | 06H  |

Notice: When it reads or writes from/to the register while the counter is in operation (RTCE = 1), follow the procedures described in "7.4.3 Reading/writing real-time clock".

www.mcu.com.cn 214 / 624 Rev.1.0.3

#### 7.3.11 Month count register (MONTH)

The MONTH register is an 8-bit register that takes a value of 1 to 12 (decimal) and indicates the count value of months. It counts up when the day counter overflows.

When data is written to this register, it is written to a buffer and then to the counter up to two cycles of  $F_{RTC}$  later. Even if the day count register overflows while this register is being written, this register ignores the overflow and is set to the value written. Set a decimal value of 01 to 12 to this register in BCD code.

The MONTH register is set by an 8-bit memory manipulation instruction. After a reset signal is generated, the value of this register becomes "01H".

Table 7-14: Format of month count register (MONTH)

| Address: 0 | x40044F57H | After reset:<br>01H | R/W |         |        |        |        |        |
|------------|------------|---------------------|-----|---------|--------|--------|--------|--------|
| Symbol     | 7          | 6                   | 5   | 4       | 3      | 2      | 1      | 0      |
| MONTH      | 0          | 0                   | 0   | MONTH10 | MONTH8 | MONTH4 | MONTH2 | MONTH1 |

Notice: When it reads or writes from/to the register while the counter is in operation (RTCE = 1), follow the procedures described in "7.4.3 Reading/writing real-time clock".

#### 7.3.12 Year count register (YEAR)

The YEAR register is an 8-bit register that takes a value of 0 to 99 (decimal) and indicates the count value of years. It counts up when the month count register (MONTH) overflows.

Values 00, 04, 08, ..., 92, and 96 indicate a leap year.

When data is written to this register, it is written to a buffer and then to the counter up to two cycles of  $F_{RTC}$  later. Even if the MONTH register overflows while this register is being written, this register ignores the overflow and is set to the value written. Set a decimal value of 00 to 99 to this register in BCD code. The YEAR register is set by an 8-bit memory manipulation instruction. After a reset signal is generated, the value of this register becomes "00H".

Table 7-15: Format of year count register (YEAR)

| Address: 0x40044F58H |        | After reset:<br>00H | R/W    | -      |       | ·     |       |       |  |
|----------------------|--------|---------------------|--------|--------|-------|-------|-------|-------|--|
| Symbol               | 7      | 6                   | 5      | 4      | 3     | 2     | 1     | 0     |  |
| YEAR                 | YEAR80 | YEAR40              | YEAR20 | YEAR10 | YEAR8 | YEAR4 | YEAR2 | YEAR1 |  |

Notice: When it reads or writes from/to the register while the counter is in operation (RTCE = 1), follow the procedures described in "7.4.3 Reading/writing real-time clock".

www.mcu.com.cn 215 / 624 Rev.1.0.3

#### 7.3.13 Alarm minute register (ALARMWM)

This register is used to set minutes of alarm.

The ALARMWM register can be set by an 8-bit memory manipulation instruction. After a reset signal is generated, the value of this register becomes "00H".

Note: Set a decimal value of 00 to 59 to this register in BCD code. If a value outside the range is set, the alarm is not detected.

Table 7-16: Format of alarm minute register (ALARMWM)

| Address: 0x40044F5AH |   | After reset:<br>00H | R/W  |      |     |     |     |     |
|----------------------|---|---------------------|------|------|-----|-----|-----|-----|
| Symbol               | 7 | 6                   | 5    | 4    | 3   | 2   | 1   | 0   |
| ALARMWM              | 0 | WM40                | WM20 | WM10 | WM8 | WM4 | WM2 | WM1 |

#### 7.3.14 Alarm hour register (ALARMWH)

This register is used to set hours of alarm.

The ALARMWH register can be set by an 8-bit memory manipulation instruction. After a reset signal is generated, the value of this register becomes "12H".

However, the value of this register is 00H if the AMPM bit is set to 1 after reset.

Notice: Set a decimal value of 00 to 23, 01 to 12, or 21 to 32 to this register in BCD code. If a value outside the range is set, the alarm is not detected.

Table 7-17: Format of alarm hour register (ALARMWH)

| Address: 0x40 | 0044F5BH | After reset:<br>12H | R/W  |      | <b>O</b> ( | ,   |     |     |
|---------------|----------|---------------------|------|------|------------|-----|-----|-----|
| Symbol        | 7        | 6                   | 5    | 4    | 3          | 2   | 1   | 0   |
| ALARMWH       | 0        | 0                   | WH20 | WH10 | WH8        | WH4 | WH2 | WH1 |

Notice: Bit 5 (WH20) of the ALARMWH register indicates AM(0)/PM(1) if AMPM = 0 (if the 12-hour system is selected).

www.mcu.com.cn 216 / 624 Rev.1.0.3

# 7.3.15 Alarm week register (ALARMWW)

This register is used to set date of alarm.

The ALARMWW register can be set by an 8-bit memory opearation instruction. After a reset signal is generated, the value of this register becomes "00H".

Table 7-18: Format of alarm week register (ALARMWW)

| Address: 0x40044F5CH |   | After reset:<br>12H | R/W |     |     |     |     |     |  |
|----------------------|---|---------------------|-----|-----|-----|-----|-----|-----|--|
| Symbol               | 7 | 6                   | 5   | 4   | 3   | 2   | 1   | 0   |  |
| ALARMWW              | 0 | WW6                 | WW5 | WW4 | WW3 | WW2 | WW1 | WW0 |  |

Here is an example of setting the alarm.

|                             |        | Day    |         |           |          |        |          |    | 12-hour display |    |   | 24-hour display |      |    |        |
|-----------------------------|--------|--------|---------|-----------|----------|--------|----------|----|-----------------|----|---|-----------------|------|----|--------|
|                             | Sunday | Monday | Tuesday | Wednesday | Thursday | Friday | Saturday |    |                 |    |   |                 |      |    |        |
| Time of alarm               | W      | W      | W       | W         | W        | W      | W        |    | Hour            |    |   |                 | Hour |    | Minute |
|                             | W      | W      | W       | W         | W        | W      | W        | 10 | 1               | 10 | 1 | 10              | 1    | 10 | 1      |
|                             | 0      | 1      | 2       | 3         | 4        | 5      | 6        |    |                 |    |   |                 |      |    |        |

### 7.3.16 Port mode register and port register

To output the multiplexed port of the RTC1HZ output pin with 1Hz, you must set "0" to the bit of the Port Mode Control Register (PMCxx), the bit of the Port Mode Register (PMxx), and the bit of the Port Register (Pxx) corresponding to each port.

The set port mode registers (PMxx), port registers (Pxx), and port mode control registers (PMCxx) differ by product. For more information, refer to "2.3 Registers for controlling port functions".

www.mcu.com.cn 217 / 624 Rev.1.0.3

## 7.4 Operation of real-time clock

# 7.4.1 Start of real-time clock operation

start configure to provide RTCEN=1 Note1 input clock RTCE=0 configure to stop counting configure RTCCL configure  $F_{\text{RTC}}$ select 12 hour system or 24 configure AMPM, hours system and interrupt CT2~CT0 (INTRTC) configure second count configure SEC register configure minute count configure MIN register configure hour count configure HOUR configure week count configure WEEK register configure DAY configure day count register configure month count configure MONTH register configure year count configure YEAR register configure clock deviation configure SUBCUD<sup>Note2</sup> calibration register clear interrupt request flag clear IF interrupt flag (Ifxx). clear interrupt mask flag clear MK interrupt flag RTCE=1<sup>Note3</sup> configure start counting No INTRTC=1? Yes end

Figure 7-2: Procedure for starting operation of real-time clock

- Note 1: First set the RTCEN bit to 1, while oscillation of the count clock (F<sub>RTC</sub>) is stable.
- Note 2: Set up the register only if the clock error must be corrected. For details about how to calculate the correction value, see "7.4.6 Example of clock error correction of real-time clock".
- Note 3: Confirm the procedure described in "7.4.2 Shifting to sleep mode after starting operation" when shifting to sleep mode without waiting for INTRTC = 1 after RTCE = 1.

## 7.4.2 Shifting to sleep mode after starting operation

Perform some of the following processing when shifting to sleep mode immediately after setting the RTCE bit to 1.

However, after setting the RTCE bit to 1, this processing is not required when shifting to sleep mode after the INTRTC interrupt has occurred.

Shifting to sleep mode when at least two cycles of the count clock (F<sub>RTC</sub>) have elapsed after setting the RTCE bit to 1 (see Figure 7-3, Example 1).

Checking by polling the RWST bit to become 1, after setting the RTCE bit to 1 and then setting the RWAIT bit to 1. Afterward, setting the RWAIT bit to 0 and shifting to sleep mode after checking again by polling that the RWST bit has become 0 (see Figure 7-3, Example 2).

Figure 7-3: Procedure for shifting to sleep/deep sleep mode after setting RTCE bit to 1

example 1

#### 7.4.3 Reading/writing real-time clock

Read or write the counter after setting "1" to RWAIT first. Set RWAIT to "0" after completion of reading or writing the counter.

start configure as SEC~Year counter RWAIT=1 stop operating, enter into read/ write mode of counter. No confirm counter wait state RWST=1? Yes read SEC read second count register read MIN read minute count register read HOUR read hour count register read WEEK Read week count register read DAY read day count register read MONTH read month count register read YEAR read year count register RWAIT=0 configure counter operation No RWST=0? Note Yes end

Figure 7-4: Procedure for reading real-time clock

Note: Be sure to confirm that RWST = 0 before setting sleep mode.

#### Notice:

- Complete the series of process of setting the RWAIT bit to 1 to clearing the RWAIT bit to 0
  within 1 second.
- The second count register (SEC), minute count register (MIN), hour count register (HOUR), week count register (WEEK), day count register (DAY), month count register (MONTH), and year count register (YEAR) may be read in any sequence. All the registers do not have to read and only some registers may be read.

www.mcu.com.cn 220 / 624 Rev.1.0.3

Figure 7-5: Procedure for reading real-time clock

Note 1: Be sure to confirm that RWST = 0 before setting sleep mode.

#### Notice:

- 1. Complete the series of operations of setting the RWAIT bit to 1 to clearing the RWAIT bit to 0 within 1 second.
- 2. When changing the values of the SEC, MIN, HOUR, WEEK, DAY, MONTH, and YEAR register while the counter operates (RTCE = 1), rewrite the values after disabling interrupt servicing INTRTC by using the interrupt mask flag register, and the WAFG, RIFG, and RTCIF flags should be cleared after the rewrite.
- 3. The second count register (SEC), minute count register (MIN), hour count register (HOUR), week count register (WEEK), day count register (DAY), month count register (MONTH), and year count register (YEAR) may be read in any sequence. All the registers do not have to read and only some registers may be read.

www.mcu.com.cn 221 / 624 Rev.1.0.3

#### 7.4.4 Setting alarm of real-time clock

Set alarm time after setting 0 to WALE (alarm operation invalid) first.

Figure 7-6: Alarm setting steps start WALE=0 alarm alignment operation invalid generate interrupt via alarm WALIE=1 alignment configure ALARMWM configure alarm minute register configure ALARMWH configure alarm hour register configure ALARMWW configure alarm week register WALE=1 alarm alignment operation valid No INTRTC=1? Yes No No WAFG=1? detect alarm Yes alignment fixed cycle interrupt alarm processing processing

Notice:

- 1. There is no limit to the order of write operations for alarm minute registers (ALARMWM), alarm hour registers (ALARMWH), and alarm week registers (ALARMWW).
- 2. Fixed-cycle interrupts and alarm-consistent interrupts use the same interrupt source (INTRTC). When using these two types of interrupts at the same time, which interrupt occurred can be judged by checking the fixed-cycle interrupt status flag (RIFG) and the alarm detection status flag (WAFG) upon INTRTC occurrence.

www.mcu.com.cn 223 / 624 Rev.1.0.3

#### 7.4.6 Example of clock error correction of real-time clock

The clock can be corrected with high accuracy when it is slow or fast, by setting a value to the clock error correction register.

Example of calculating the correction value

The correction value used when correcting the count value of the internal counter (16-bit) is calculated by using the following equation: If a correctable range is -4165.6 ppm or lower and 4165.6 ppm or higher, set 0 to DEV.

(When DEV=0)

Correction value Note=Number of correction counts in 1 minute  $\div$  3=(Oscillation frequency  $\div$  Target frequency-1)×32768×60 $\div$ 3

(When DEV=1)

Correction value<sup>Note</sup>=Number of correction counts in 1 minute=(Oscillation frequency÷Target frequency-1) ×32768×60

Note: The correction value is the clock error correction value calculated by using bits 12 to 0 of the clock error correction register (SUBCUD).

(When F12=0) correction value ={(F11,F10,F9,F8,F7,F6,F5,F4,F3,F2,F1,F0)-1} $\times$ 2 (When F12=0) correction value = -{(/F11,/F10,/F9,/F8,/F7,/F6,/F5,/F4,/F3,/F2,/F1,/F0)+1} $\times$ 2 When (F12 $\times$ F0)=(\*,0,0,0,0,0,0,0,0,0,0,0,0,\*), clock error correction is not performed. "\*" is 0 or 1. /F12 $\times$ /F0 are bit-inverted values ("000000000011" when "111111111100").

#### Remark:

- 1. The correction value is 2,4,6,8,.....,8186, 8188 or -2,-4,-6,-8,.....,-8186,-8188.
- 2. The oscillation frequency is the value of the counting clock (FRTC), and can be calculated by the following equation: The output frequency of the RTC1HZ pin×32768 when the clock error correction register is set to its initial value (00H).
- 3. The target frequency is the frequency resulting after correction performed by using the clock error correction register.

www.mcu.com.cn 224 / 624 Rev.1.0.3

Correction example

Example of correcting from 32767.4Hz to 32768Hz (32767.4Hz+18.3ppm)

[Measuring the oscillation frequency]

When the watch error correction register (SUBCUD) is the initial value ("0000H"), the oscillation frequency of each product is measured by outputting a signal of approximately 1Hz from the RTC1HZ pin<sup>Note</sup>.

Note: For the setting of RTC1Hz output, please refer to "7.4.5 1Hz output of real-time clock".

[Calculating the correction value]

(When the output frequency of the RTC1HZ pin is 0.9999817Hz)

Oscillation frequency =  $32768 \times 0.9999817 \approx 32767.4$ Hz

Suppose the target frequency is 32768Hz (32767.4Hz+18.3ppm) and DEV=1. An equation for calculating the correction value when the DEV bit is "1" is applied.

Correction value=Number of correction counts in 1 minute=(Oscillation frequency÷Target frequency-1)×32768×60=(32767.4÷32768-1) ×32768×60= -36

[Calculating the values to be set to (F12~F0)]

(When the correction value= -36)

If the correction value is less than 0 (when faster), assume F12=1. Calculating is based on correction values (F11~F0).

```
-\{(/F11\sim/F0)-1\}\times 2=-36
(/F11\sim/F0)=17
(/F11\sim/F0)=(0,0,0,0,0,0,0,1,0,0,0,1)
(F11\sim F0)=(1,1,1,1,1,1,1,0,1,1,1,0)
```

Therefore, the correction from 32767.4Hz to 32768Hz (32767.4Hz +18.3ppm) is as follows:

If by DEV=1 and correction value=–36 (bit12~0 of the SUBCUD register:1,1,1,1,1,1,1,1,1,1,1,0) to set the correction register, you can correct it to 32768Hz (0ppm).

# **Chapter 8 15-Bit Interval Timer**

#### 8.1 Function of 15-bit interval timer

An interrupt (INTIT) is generated at any previously specified time interval. It can be utilized for wakeup from deep sleep mode.

#### 8.2 Structure of 15-bit interval timer

The 15-bit interval timer consists of the following hardware.

Table 8-1: Structure of 15-bit interval timer

| Item             | Structure                                     |  |  |  |  |
|------------------|---|--|--|--|--|

## 8.3 Registers for controlling 15-bit interval timer

The 15-bit interval timer is controlled by the following registers.

Peripheral enable register 0 (PER0).

Real-time clock selection register (RTCCL)

15-bit interval timer control register (ITMC)

### 8.3.1 Peripheral enable register 0 (PER0)

The PER0 register is a register that sets a clock that is allowed or prohibited to supply to each peripheral hardware. Reduce power consumption and noise by stopping clock supply to unused hardware.

When using a 15-bit interval timer, bit7 (RTCEN) must be set to "1". The PER0 register is set by an 8-bit memory manipulation instruction. After the reset signal is generated, the value of this register changes to "00H".

Table 8-2: Format of peripheral enable register 0 (PER0)

| Address: 0x40020420 |       | After reset: | R/W   |         |        |        |        |        |

www.mcu.com.cn 228 / 624 Rev.1.0.3

#### 8.3.3 15-bit interval timer control register (ITMC)

This register is used to set up the starting and stopping of the 15-bit interval timer operation and to specify the timer compare value.

The ITMC register is set by a 16-bit memory manipulation instruction.

After a reset signal is generated, the value of this register becomes "7FFFH".

Table 8-4: Format of 15-bit interval timer control register (ITMC)

Address: 0x40044F50

Example interrupt cycles when 001H or 7FFFH is specified for ITCMP14~ITCMP0

 ITCMP14~ITCMP0=0001H, count clock: F<sub>SUB</sub>=32.768KHz 1/32.768[KHz]×(1+1)=0.06103515625[ms]≈61.03[us]

ITCMP14~ITCMP0=7FFFH, count clock: F<sub>SUB</sub>=32.768KHz 1/32.768[KHz]×(32767+1)=1000[ms]

#### Notice:

- 1. Before changing the RINTE bit from "1" to "0", use the interrupt mask flag register to disable the INTIT interrupt servicing. When the operation starts (from "0" to "1") again, clear the ITIF flag, and then enable the interrupt servicing.
- 2. The value read from the RINTE bit is applied one count clock cycle after setting the RINTE bit.
- 3. After shifting from sleep mode to normal operation mode, if you want to set the ITMC register and enter sleep mode again, you must confirm that the write value of the ITMC register is reflected or set the ITMC registers or wait that more than one clock of the count clock has elapsed before shifting to sleep mode.
- 4. Only change the setting of the ITCMP14 to ITCMP0 bits when RINTE = 0. However, it is possible to change the settings of the ITCMP14 to ITCMP0 bits at the same time as when changing RINTE from "0" to "1" or "1" to "0".

www.mcu.com.cn 229 / 624 Rev.1.0.3

## 8.4 Operation of 15-bit interval timer

#### 8.4.1 Operation timing of 15-bit interval timer

The count value specified for the ITCMP14 to ITCMP0 bits is used as an interval to operate a 15-bit interval timer that repeatedly generates interrupt requests (INTIT). When the RINTE bit is set to "1", the 15-bit counter starts counting.

When the 15-bit counter value matches the value specified for the ITCMP14 to ITCMP0 bits, the 15-bit counter value is cleared to 0, counting continues, and an interrupt request signal (INTIT) is generated at the same time.

The basic operation of the 15-bit interval timer is as follows Figure 8-2.

Figure 8-2: Operation timing of 15-bit interval timer (ITCMP14~ITCMP0=0FFH, count clock: F<sub>SUB</sub>=32.768KHz)

www.mcu.com.cn 230 / 624 Rev.1.0.3

# 8.4.2 Start of count operation and re-enter to sleep mode after returned from sleep mode

When setting the RINTE bit after returned from sleep mode and entering sleep mode again, write 1 to the RINTE bit, and confirm the written value of the RINTE bit is reflected or wait for at least one cycle of the count clock. Then, enter sleep mode.

After setting RINTE to 1, confirm by polling that the RINTE bit has become 1, and then enter sleep mode (see Example 1 in the figure below).

After setting RINTE to 1, wait for at least one cycle of the count clock and then enter sleep mode (see Example 2 in the figure below).

# Chapter 9 Clock Output/Buzzer Output Controller

#### 9.1 Function of clock output/buzzer output controller

Clock output is the function of outputting the clock provided to the peripheral IC, and buzzer output is the function of outputting the buzzer frequency square wave.

This product has two clock output/buzzer output pins that can be selected to be used as clock output or buzzer output from any pin other than RESETB.

The CLKBUZn pin outputs the clock selected by the clock output selection register n (CKSn).

The block diagram of the clock output/buzzer output controller is shown in Figure 9-1.

Notice: The subsystem clock ( $F_{SUB}$ ) cannot be output from the CLKBUZn pin when the RTCLPC bit of the subsystem clock supply mode control register (OSMC) is "1" and in the SLEEP mode in which the CPU is running with the subsystem clock ( $F_{SUB}$ ).

Remark: n=0, 1.

Figure 9-1: Block diagram of clock output/buzzer output controller

Remark: For the frequencies that can be output from CLKBUZ0 and CLKBUZ1 pins, please refer to "AC Characteristics" in the data sheet.

# 9.2 Structure of clock output/buzzer output controller

The clock output/buzzer output controller consists of the following hardware.

Table 9-1: Registers for controlling clock output/buzzer output controller

| Item | Structure   |
|------|---|
|      | Clock output select registers n (CKSn) Port mode control register (PMCxx), Port mode register (PMxx), Port multiplexing control register (PxxCFG) |

www.mcu.com.cn 233 / 624 Rev.1.0.3

# 9.3 Registers for controlling clock output/buzzer output controller

## 9.3.1 Clock output select register n (CKSn)

These registers set output enable/disable for clock output or for the buzzer frequency output pin (CLKBUZn), and set the output clock.

Select the clock to be output from the CLKBUZn pin by using the CKSn register. The CKSn register is set by an 8-bit memory manipulation instruction. After a reset signal is generated, the value of this register becomes "00H".

Table 9-2: Format of clock output select register n (CKSn)

| 0     | 1     | 0     | 1     | F <sub>MAIN</sub> /2 <sup>11</sup> |
| 0     | 1     | 1     | 0     | F <sub>MAIN</sub> /2 <sup>12</sup> |
| 0     | 1     | 1     | 1     | F <sub>MAIN</sub> /2 <sup>13</sup> |
| 1     | 0     | 0     | 0     | F <sub>SUB</sub>                   |
| 1     | 0     | 0     | 1     | F <sub>SUB</sub> /2                |
| 1     | 0     | 1     | 0     | F <sub>SUB</sub> /2 <sup>2</sup>   |
| 1     | 0     | 1     | 1     | F <sub>SUB</sub> /2 <sup>3</sup>   |
| 1     | 1     | 0     | 0     | F <sub>SUB</sub> /2 <sup>4</sup>   |
| 1     | 1 0   |       | 1     | F <sub>SUB</sub> /2 <sup>5</sup>   |
| 1     | 1     | 1     | 0     | F <sub>SUB</sub> /2 <sup>6</sup>   |
| 1     | 1     | 1     | 1     | F <sub>SUB</sub> /2 <sup>7</sup>   |

Note: Use the output clock within a range of 16 MHz. For details, please refer to "AC Characteristics" in the data sheet.

#### Notice:

- 1. Change the output clock after disabling clock output (PCLOEn = 0).
- 2. To shift to deep sleep mode when the main system clock is selected (CSELn = 0), set PCLOEn = 0 before executing the WFI instruction. When the subsystem clock is selected (CSELn = 1), PCLOEn = 1 can be set because the clock can be output while the RTCLPC bit of the subsystem clock supply mode control (OSMC) register is set to 0 and moreover while deep sleep mode is set.

www.mcu.com.cn 234 / 624 Rev.1.0.3

3. It is not possible to output the subsystem clock  $(F_{SUB})$  from the CLKBUZn pin while the RTCLPC bit of the subsystem clock supply mode control register (OSMC) is set to 1 and moreover while sleep mode is set with the subsystem clock  $(F_{SUB})$  selected as CPU clock.

#### Remark:

1. n=0, 1

2.  $F_{MAIN}$ : Main system clock frequency.

 $\mathsf{F}_{\mathsf{SUB}}$  : Subsystem clock frequency.

www.mcu.com.cn 235 / 624 Rev.1.0.3

# 9.3.2 Registers for controlling clock output/buzzer output port functions

This product can multiplex the clock output/buzzer output function CLKBUZ0/CLKBUZ1 to any port except RESETB. To use the clock output/buzzer output function, the port multiplexing function configuration register (PxxCFG), port register (Pxx), port mode register (PMxx), and port mode control register (PMCxx) must be set. For details, refer to "Chapter 2 Port Function".

A multiplexed port configured as a clock output/buzzer output pin must have its corresponding Port Register (Pxx), Port Mode Register (PMxx) bits and Port Mode Control Register (PMCxx) bits set to "0".

(Example) Using P20 as clock output/buzzer output (CLKBUZ0).

- (1) Set the bit P20 of port register 2 to "0".
- (2) Set the PM20 bit of port mode register 2 to "0".
- (3) Set the PMC20 bit of port mode control register 2 to "0".
- (4) Set "0x18" to port multiplexing function configuration register P20CFG.

(Example) Using P15 as clock output/buzzer output (CLKBUZ1).

- (1) Set the bit P15 of the port register 1 to "0".
- (2) Set the PM15 bit of port mode register 1 to "0".
- (3) Set "0" to PMC15 bit of port mode control register 1.
- (4) Set "0x19" to port multiplexing function configuration register P15CFG.

www.mcu.com.cn 236 / 624 Rev.1.0.3

## 9.4 Operation of clock output/buzzer output controller

One pin can be used as clock output or buzzer output.

The CLKBUZ0 pin outputs a clock/buzzer selected by the clock output select register 0 (CKS0).

The CLKBUZ1 pin outputs a clock/buzzer selected by the clock output select register 1 (CKS1).

#### 9.4.1 Operation as output pin

The CLKBUZn pin is output as the following procedure.

- ① Set the bit of the port register (Pxx), port mode register (PMxx) and port mode control register (PMCxx) corresponding to the port used as CLKBUZn pin to "0". Set the port multiplexing function configuration register (PxxCFG).
- ② Select the output frequency with bits 0 to 3 (CCSn0 to CCSn2, CSELn) of the clock output select register (CKSn) of the CLKBUZn pin (output in disabled status).
- ③ Set bit 7 (PCLOEn) of the CKSn register to 1 to enable clock/buzzer output.

#### Remark:

- The controller used as clock output starts or stops the clock output after 1 clock after the clock output (PCLOEn bit) is enabled or disabled. At this time, pulses with a narrow width are not output. Figure 9-2 shows enabling or stopping output using the PCLOEn bit and the timing of outputting the clock.
- 2. n=0, 1.

Figure 9-2: CLKBUZn pin output clock timing

## 9.5 Cautions for clock output/buzzer output controller

When the main system clock is selected for the CLKBUZn output (CSE=0), if deep sleep mode is entered within 1.5 clock cycles output from the CLKBUZn pin after the output is disabled (PCLOEn=0), the CLKBUZn output width becomes narrower.

www.mcu.com.cn 237 / 624 Rev.1.0.3

# **Chapter 10 Watch Dog Timer**

## 10.1 Function of watchdog timer

The counting operation of the watchdog timer is set by the option byte (000C0H). The watchdog timer operates on the low-speed internal oscillator clock ( $F_{IL}$ ).

The watchdog timer is used to detect an inadvertent program loop. An internal reset signal is generated when a program loop is detected.

Program loop is detected in the following cases.

- (1) If the watchdog timer counter overflows
- (2) If data other than "ACH" is written to the WDTE register
- (3) If data is written to the WDTE register during a window close period

When a reset occurs due to the watchdog timer, bit 4 (WDTRF) of the reset control flag register (RESF) is set to "1". For details of the RESF register, please refer to "Chapter 19 Reset Function". When  $75\%+1/2F_{IL}$  of the overflow time is reached, an interval interrupt can be generated.

### 10.2 Structure of watch dog timer

The watchdog timer includes the following hardware.

Table 10-1: Structure of watch dog timer

| Item             | Structure                             |
|------------------|---------------------------------------|
| Counter          | Internal counter (17-bit)             |
| Control register | Watchdog timer enable register (WDTE) |

The operation of the counter is controlled by means of option bytes as well as setting the overflow time, the window opening period and the interval interruption.

Table 10-2: Setting of option bytes and watchdog timer

| 3  | 1 7                              |
|--|----------------------------------|
| Setting of watchdog timer                                | Option byte (000C0H)             |
| Watchdog timer interval interrupt                        | bit7 (WDTINT)                    |
| Setting of window open period                            | bit6 and bit5 (WINDOW1, WINDOW0) |
| Watchdog timer counter operation control                 | bit4 (WDTON)                     |
| Overflow time of watchdog timer                          | bit3~1 (WDCS2~WDCS0)             |
| Watchdog timer counter operation control (in sleep mode) | bit0 (WDSTBYON)                  |

Remark: For the option byte, see "Chapter 24 Option Byte".

Figure 10-1: Block diagram of watchdog timer

Remark: F<sub>IL</sub>: Low-speed on-chip oscillator clock frequency

www.mcu.com.cn 239 / 624 Rev.1.0.3

### 10.3 Registers for controlling watchdog timer

The watchdog timer is controlled by the watchdog timer enable register (WDTE).

### 10.3.1 Watchdog timer enable register (WDTE)

Writing "ACH" to the WDTE register clears the watchdog timer counter and starts counting again. The WDTE register is set by an 8-bit memory manipulation instruction. Reset signal generation sets this register to "9AH" or "1AH" Note.

Table 10-3: Format of watchdog timer enable register (WDTE)

| Address: 0x40021001 |   | After reset: 9AH/1AH <sup>Note</sup> |   | R/W |   |   |   |   |
|---------------------|---|--------------------------------------|---|-----|---|---|---|---|
| Symbol              | 7 | 6                                    | 5 | 4   | 3 | 2 | 1 | 0 |
| WDTE                |   |                                      |   |     |   |   |   |   |

Note: The WDTE register reset value differs depending on the WDTON bit setting value of the option byte (000C0H). To operate watchdog timer, set the WDTON bit to 1.

| WDTON bit setting value                     | WDTE register reset value |
|---|---------------------------|
| 0 (watchdog timer count operation disabled) | 1AH                       |
| 1 (watchdog timer count operation enabled)  | 9AH                       |

#### Remark:

- 1. If a value other than "ACH" is written to the WDTE register, an internal reset signal is generated.
- 2. The value read from the WDTE register is 9AH/1AH (this differs from the written value ("ACH")).

www.mcu.com.cn 240 / 624 Rev.1.0.3

# 10.3.2 LOCKUP control register (LOCKCTL) and its protection register (PRCR)

The LOCKCTL register is a configuration register for controlling the Cortex-M0+ LockUp function to operate the watchdog timer, and PRCR is its write-protect register.

The LOCKCTL, PRCR registers are set by an 8-bit memory manipulation instruction.

After generating a reset signal, the values of the LOCKCTL, PRCR register change to "00H".

Table 10-4: Format of LOCKUP control register (LOCKCTL) and its protection register (PRCR) (1/2)

| Address: 4 | 0020405H | After reset:<br>01H | R/W |   |   |   |   |            |
|------------|----------|---------------------|-----|---|---|---|---|------------|
| Symbol     | 7        | 6                   | 5   | 4 | 3 | 2 | 1 | 0          |
| LOCKCTL    | 0        | 0                   | 0   | 0 | 0 | 0 | 0 | lockup_rst |

| lockup_rst | Configuration of LOCKUP function  |
|------------|-----------------------------------|
| 0          | LOCKUP does not cause a WDT reset |
| 1          | LOCKUP causes the WDT to reset    |

Table 10-4: Format of LOCKUP control register (LOCKCTL) and its protection register (PRCR) (2/2)

| Address: 40020406H |   | After reset:<br>00H | R/W |            |   |   |   |      |

| Other       | PRCR is not writable     |

www.mcu.com.cn 241 / 624 Rev.1.0.3

# 10.3.3 WDTCFG configuration register (WDTCFG0/1/2/3)

The WDTCFG configuration register is the register that determines whether to force the watchdog timer to run.

WDTCFG register is set by 8-bit memory operation instruction.

After the reset signal is generated, the value of WDTCFG register becomes "00H".

Table 10-5: WDTCFG configuration register (WDTCFG0/1/2/3)

| Address:4002040CH | After reset:<br>00H | WO | .9    |    | , , , |   |   |

www.mcu.com.cn 242 / 624 Rev.1.0.3

## 10.4 Operation of watchdog timer

#### 10.4.1 Operational control of watchdog timer

- 1. When using the watchdog timer, set the following items by option byte (000C0H):
  - (1) The bit 4 (WDTON) of the option byte (000C0H) must be set to "1" to enable the watchdog timer count to operate (the counter starts operating after the reset is released) (refer to Chapter 24 Option Byte for details).

| WDTON | Counter of watchdog timer  |  |  |  |  |
|-------|--|--|--|--|--|
| 0     | Disables counting operation (stop counting after reset released) |  |  |  |  |
| 1     | Enables counting operation (start counting after release reset)  |  |  |  |  |

- (2) The overflow time must be set by bit3~1 (WDCS2~WDCS0) of the option byte (000C0H) (refer to 10.4.2 and Chapter 24 Option Byte for details).
- (3) The window opening period must be set by bit6 and bit5 (WINDOW1, WINDOW0) of the option byte (000C0H) (refer to 10.4.2 and Chapter 24 Option Byte for details).
- 2. After the reset is released, the watchdog timer starts counting.
- 3. After starting counting and before the overflow time set by the option byte, writing "ACH" to the watchdog timer enable register (WDTE) clears the watchdog timer and starts counting again.
- 4. Thereafter, writes to WDTE registers after the second time after the reset must be performed while the window is open. If you write the WDTE register while the window is closed, an internal reset signal is generated.
- 5. If you do not write "ACH" to the WDTE register and exceed the overflow time, an internal reset signal is generated. An internal reset signal is generated if:
  - (1) If data other than "ACH" is written to the WDTE register

#### Remark:

- 1. When data is written to the watchdog timer enable register (WDTE) for the first time after reset release, the watchdog timer is cleared in any timing regardless of the window open time, as long as the register is written before the overflow time, and the watchdog timer starts counting again.
- 2. After "ACH" is written to the WDTE register, an error of up to 2 F<sub>IL</sub> clocks may occur before the watchdog timer is cleared.
- 3. The watchdog timer can be cleared immediately before the count value overflows.
- 4. As shown below, the watchdog timer operates in sleep or deep sleep mode depending on the set value of bit0 (WDSTBYON) of the option byte (000C0H).

|                 | WDSTBYON=0                        | WDSTBYON=1                            |  |
|-----------------|-----------------------------------|---------------------------------------|--|
| Sleep mode      | Stop operation of watchdog timer. | Continue operation of watchdag timer  |  |
| Deep sleep mode | Stop operation of watchdog timer. | Continue operation of watchdog timer. |  |

- 5. When the WDSTBYON bit is "0", restart the watchdog timer count after the sleep or deep sleep mode released. At this point, the counter is cleared to "0" and the count begins.
- 6. When operating with the X1 oscillation clock after releasing the deep sleep mode, the CPU starts operating after the oscillation stabilization time has elapsed.
- 7. Therefore, if the period between the deep sleep mode release and the watchdog timer overflow

is short, an overflow occurs during the oscillation stabilization time, causing a reset. Consequently, set the overflow time in consideration of the oscillation stabilization time when operating with the X1 oscillation clock and when the watchdog timer is to be cleared after the deep sleep mode release by an interval interrupt.

## 10.4.2 Setting overflow time of watchdog timer

Set the overflow time of the watchdog timer by using bits 3 to 1 (WDCS2 to WDCS0) of the option byte (000C0H).

If an overflow occurs, an internal reset signal is generated. The present count is cleared and the watchdog timer starts counting again by writing "ACH" to the watchdog timer enable register (WDTE) during the window open period before the overflow time. The following overflow times can be set.

Table 10-6: Setting of overflow time of watchdog timer

| WDCS2 | WDCS1 | WDCS0 | Overflow time of watchdog timer (When F <sub>IL</sub> =20KHz(MAX.)) |
|-------|-------|-------|---|
| 0     | 0     | 0     | 2 <sup>6</sup> /F <sub>IL</sub> (3.2ms)                             |
| 0     | 0     | 1     | 2 <sup>7</sup> /F <sub>I</sub> ∟ (6.4ms)                            |
| 0     | 1     | 0     | 2 <sup>8</sup> /F <sub>IL</sub> (12.8ms)                            |
| 0     | 1     | 1     | 2 <sup>9</sup> /F <sub>IL</sub> (25.6ms)                            |
| 1     | 0     | 0     | 2 <sup>11</sup> /F <sub>IL</sub> (102.4ms)                          |
| 1     | 0     | 1     | 2 <sup>13</sup> /F <sub>IL</sub> (409.6ms)                          |
| 1     | 1     | 0     | 2 <sup>14</sup> /F <sub>IL</sub> (819.2ms)                          |
| 1     | 1     | 1     | 2 <sup>16</sup> /F <sub>IL</sub> (3276.8ms)                         |

Remark: FIL: Low-speed on-chip oscillator clock frequency

www.mcu.com.cn 245 / 624 Rev.1.0.3

### 10.4.3 Setting window open period of watchdog timer

Set the window open period of the watchdog timer by using bits 6 and 5 (WINDOW1, WINDOW0) of the option byte (000C0H). The outline of the window is as follows:

- (1) If "ACH" is written to the watchdog timer enable register (WDTE) during the window open period, the watchdog timer is cleared and starts counting again.
- (2) Even if "ACH" is written to the WDTE register during the window close period, an abnormality is detected and an internal reset signal is generated.

Remark: When data is written to the WDTE register for the first time after reset release, the watchdog timer is cleared in any timing regardless of the window open time, as long as the register is written before the overflow time, and the watchdog timer starts counting again.

The window open period can be set is as follows.

Table 10-7: Setting window open period of watchdog timer

| WINDOW1 | WINDOW0 | Window open period of watchdog timer |
|---------|---------|--------------------------------------|
| 0       | -       | Settings are disabled.               |
| 1       | 0       | 75%                                  |
| 1       | 1       | 100%                                 |

#### Remark:

- 1. When bit 0 (WDSTBYON) of the option byte (000C0H) = 0, the window open period is 100% regardless of the values of the WINDOW1 and WINDOW0 bits.
- 2. If the overflow time is set to  $2^9/F_{1L}$ , the window close time and open time are as follows.

|                   | Setting of window open period |          |  |  |  |  |
|-------------------|-------------------------------|----------|--|--|--|--|
| 75% 100%          |                               |          |  |  |  |  |
| Window close time | 0~12.8ms                      | None     |  |  |  |  |
| Window open time  | 12.8~25.6ms                   | 0~25.6ms |  |  |  |  |

<When window open period is 50%>

(1) Overflow time:

$$2^{9}/F_{1L}$$
 (Max.) =  $2^{9}/20$ KHz (Max.) =  $25.6$ ms

(2) Window close time:

$$0\sim2^9/F_{1L}$$
 (Min.) × (1-0.75) =0~29/10KHz×0.25=0~12.8ms

(3) Window open time:

$$2^{9}/F_{IL}$$
 (Min.) × (1-0.75) ~ $2^{9}/F_{IL}$  (Max.) =12.8~25.6ms

www.mcu.com.cn 246 / 624 Rev.1.0.3

#### 10.4.4 Setting watchdog timer interval interrupt

Depending on the setting of bit 7 (WDTINT) of an option byte (000C0H), an interval interrupt (INTWDTI) can be generated when  $75\%+1/2F_{IL}$  of the overflow time is reached.

Table 10-8: Setting of watchdog timer interval interrupt

| WDTINT | Use of watchdog timer interval interrupt   |  |  |
|--------|--|--|--|
| 0      | Interval interrupt is not used.  |  |  |
| 1      | Interval interrupt is generated when 75%+1/2F <sub>IL</sub> of the overflow time is reached. |  |  |

#### Remark:

- 1. When operating with the X1 oscillation clock after releasing the deep sleep mode, the CPU starts operating after the oscillation stabilization time has elapsed. Therefore, if the period between the deep sleep mode release and the watchdog timer overflow is short, an overflow occurs during the oscillation stabilization time, causing a reset. Consequently, set the overflow time in consideration of the oscillation stabilization time when operating with the X1 oscillation clock and when the watchdog timer is to be cleared after the deep sleep mode release by an interval interrupt.
- 2. The watchdog timer continues counting even after INTWDTI is generated (until "ACH" is written to the watchdog timer enable register (WDTE)). If "ACH" is not written to the WDTE register before the overflow time, an internal reset signal is generated.

#### 10.4.5 Operation of watchdog timer during LOCKUP

When lockup\_rst bit of the lockup control register lockcTL is set to 1, once the kernel enters the LOCKUP state, the low-speed internal oscillator begins to oscillate, the watchdog timer automatically starts operating, and the overflow time control bit (WDCS2~WDCS0) is set to 3'b010, that is, the overflow time is set to 12.8ms.

# 10.4.6 Operation of watchdog timer when WDTCFG is not configured

When WDTCFG is not configured, the watchdog timer will automatically start running. The overflow time is determined by the overflow time control bit (WDCS2~WDCS0) in the option byte.

www.mcu.com.cn 247 / 624 Rev.1.0.3

# **Chapter 11 A/D Converter**

The number of analog input channels of the A/D converter varies from product to product; refer to the corresponding product datasheet for detailed pinout.

#### 11.1 Function of A/D converter

The A/D converter is used to convert analog input signals into digital values, including the following functions.

- (1) 12-bit resolution A/D conversion
- (2) Select 1 channel of analog input from ANI0~ANI19, V internal reference voltage and temperature sensor, and repeat the A/D conversion with 12-bit resolution. An interrupt request (INTAD) is generated for each end of 1 A/D conversion (in the case of the selection mode).

Various A/D conversion modes are set by the combination of modes as described below.

|                | Cofforo trioror                   | Chart the conversion with poftware energians   |  |  |
|----------------|-----------------------------------|--|--|--|
|                | Software trigger                  | Start the conversion with software operations.   |  |  |
| Trigger mode   | Hardware trigger no-<br>wait mode | Conversion is started by detecting a hardware trigger.   |  |  |
| ggoouc         | Hardware trigger wait mode        | In the conversion standby state where the A/D power supply is cut off, the power supply is turned on by detecting a hardware trigger, and the conversion starts automatically after the A/D power supply stabilization waiting time. |  |  |
| Channel        | Select mode                       | Select 1 channel of analog input for A/D conversion.   |  |  |
| selection mode | Scan mode                         | Performs A/D conversion of 4 channels of analog input in sequence. Can select 4 consecutive channels from ANI0 to ANI15 as analog inputs.  |  |  |
| Conversion     | Single conversion mode            | Performs 1 A/D conversion for the selected channel.  |  |  |
| mode           | Consecutive conversion mode       | Performs continuous A/D conversion for the selected channel until stopped by the software.   |  |  |
| Sampling time  | Samle clock 4/8<br>ADCLKs         | The sampling time can be selected via the ADSMPWAIT register, which uses 4 conversion clocks ( $F_{AD}$ ) by default.  |  |  |

Figure 11-1: Block diagram of A/D converter

Remark: For the selection of analog input channel ANIx, please refer to 11.2.6 Analog input channel specification register (ADS).

## 11.2 Registers for controlling A/D converter

The A/D converter is controlled by the following registers:

Register base address: CSC\_BASE=4002\_0420H;ADC\_BASE=4004\_5000H;PORT\_BASE=4004\_0000H

| Register name | Register description                                      | R/W | Reset value | Register address |
|---------------|---|-----|-------------|------------------|
| PER0          | Peripheral enable register 0                              | R/W | 00H         | CSC_BASE+20H     |
| ADM0          | A/D converter mode register 0                             | R/W | 00H         | ADC_BASE+00H     |
| ADM1          | A/D converter mode register 1                             | R/W | 00H         | ADC_BASE+02H     |
| ADM2          | A/D converter mode register 2                             | R/W | 00H         | ADC_BASE+04H     |
| ADTRG         | A/D converter trigger mode register                       | R/W | 00H         | ADC_BASE+06H     |
| ADS           | Analog input channel specification register               | R/W | 00H         | ADC_BASE+08H     |
| ADLL          | Conversion result comparison lower limit setting register | R/W | 00H         | ADC_BASE+0AH     |
| ADUL          | Conversion result comparison upper limit setting register | R/W | 00H         | ADC_BASE+0BH     |
| ADCR          | 12-bit A/D conversion result register                     | R   | 0000H       | ADC_BASE+0EH     |
| ADCRH         | 8-bit A/D conversion result register                      | R   | 00H         | ADC_BASE+0FH     |
| ADSMPWAIT     | A/D converter sampling time extension control register    | R/W | 00H         | ADC_BASE+15H     |
| PMCn          | Port mode control register                                | R/W | Note 1      | PORT_BASE+Note1  |

R: read only, W: write only, R/W: both read and write

Remark: When selecting a channel by the ADS register, you need to configure the PMC register of the channel pin as an analog channel.

www.mcu.com.cn 250 / 624 Rev.1.0.3

## 11.2.1 Peripheral enable register 0 (PER0)

The PER0 register is the register that sets whether to enable or disable the supply of clocks to each peripheral hardware. Reduce power consumption and noise by stopping clocks to hardware that is not in use.

To use the A/D converter, bit5 (ADCEN) must be set to "1".

The PER0 register is set by an 8-bit memory manipulation instruction.

After a reset signal is generated, the value of this register becomes "00H".

Table 11-1: Table of peripheral enable register 0 (PER0)

| Reset value: 00H |       | R/W    |       |         |        |        |        |        |
|------------------|-------|--------|-------|---------|--------|--------|--------|--------|
|                  | 7     | 6      | 5     | 4       | 3      | 2      | 1      | 0      |
| PER0             | RTCEN | IRDAEN | ADCEN | IICA0EN | SCI1EN | SCI0EN | TM41EN | TM40EN |

| ADCEN | Control of the input clock for the A/D converter  |
|-------|---|
| 0     | Stop to supply the input clock.  The SFR used by the A/D converter cannot be written.  The A/D converter is in the reset state. |
| 1     | Supply the input clock.  • The SFR used by the A/D converter can be read and written.   |

Remark: When setting the A/D converter, be sure to set the following registers first while the ADCEN bit is set to 1. If ADCEN = 0, the values of the A/D converter control registers are cleared to their initial values and writing to them is ignored (except for port mode control register (PMCxx)).

www.mcu.com.cn 251 / 624 Rev.1.0.3

## 11.2.2 A/D converter mode register 0 (ADM0)

This register sets the clock for A/D converter, and starts/stops conversion. The ADM0 register is set by an 8-bit memory manipulation instruction.

After a reset signal is generated, the value of this register becomes "00H".

Table 11-2: Format of A/D converter mode register 0 (ADM0)

Reset value: 00H R/W

|      | 7    | 6 | 5   | 4   | 3   | 2 | 1 | 0    |
|------|------|---|-----|-----|-----|---|---|------|
| ADM0 | ADCS | 0 | FR2 | FR1 | FR0 | 0 | 0 | ADCE |

| ADCS | A/D conversion operation control  |  |  |
|------|---|--|--|
| 0    | Stops conversion [When read] Stop conversion/standby status   |  |  |
| 1    | Enables conversion [When read] While in the software trigger mode: Conversion operation status While in the hardware trigger wait mode: A/D power supply stabilization wait status+conversion operation |  |  |

| ADCE | A/D voltage comparator operation control  |  |
|------|---|--|
| 0    | Stops A/D voltage comparator operation.   |  |
| 1    | Enables A/D voltage comparator operation. |  |

#### Remark:

- 1. For details of the FR2~FR0 bits and A/D conversion, please refer to "Table 11-5 A/D Conversion Time Selection".
- 2. It takes 2 µs from the start of operation for the operation to stabilize. While in the software trigger mode or hardware trigger no-wait mode, when the ADCS bit is set to 1 after 2 µs or more has elapsed from the time ADCE bit is set to 1, the conversion result is valid. Otherwise, ignore data of the conversion. In hardware-triggered wait mode, a wait time of 2us is guaranteed by design.

#### Notice:

- 1. Change the FR2~FR0 bits while conversion is stopped (ADCS = 0).
- 2. Do not set the ADCS bit to 1 and the ADCE bit to 0.
- 3. Do not change the ADCS and ADCE bits from 0 to 1 by using an 8-bit manipulation instruction. You must follow the procedure in "11.5 A/D converter setup flowchart".

Table 11-3: ADCS bit and ADCE bit settings

| ADCS | ADCE | A/D conversion operation   |
|------|------|----------------------------|
| 0    | 0    | Conversion stop state      |
| 0    | 1    | Conversion standby state   |
| 1    | 0    | Prohibit settings.         |
| 1    | 1    | Conversion operating state |

### Table 11-4: ADCS bit set and clear conditions

|                                  | A/D conversion | mode                       | Set conditions        | Clear conditions  |  |
|----------------------------------|----------------|----------------------------|-----------------------|---|--|
|                                  |                | Continuous conversion mode |                       | When writing "0" to the ADCS bit  |  |

|                                  | Scan mode      | Continuous conversion mode | input hardware        | When writing "0" to the ADCS bit  |  |
|                                  |                | Single conversion mode     |                       | <ul> <li>When writing "0" to the ADCS bit</li> <li>Automatically clears to "0" when the set 4-channel conversion is completed.</li> </ul> |  |

Figure 11-2: Diagram of using various modes of A/D

Note 1: In software trigger mode or hardware trigger no-wait mode, it takes at least 2us (TBD) to rise from the ADCS bit to the ADCS bit to stabilize the internal circuitry.

Note 2: In hardware trigger wait mode, the A/D power supply stabilization time of 1us is guaranteed by design.

#### Notice:

- 1. To use the hardware trigger wait mode, setting the ADCS bit to "1" is prohibited (it is automatically switched to "1" when a hardware trigger signal is detected). However, the ADCS bit can be set to "0" in order to set the standby state for A/D conversion.
- 2. The ADCE bit must be overridden when the ADCS bit is "0" (Stop Transition/Transition Standby).
- 3. In order to end the A/D conversion, the hardware trigger interval must be set at least to the following time:

Hardware trigger no-wait mode: 2 F<sub>CLK</sub> clocks +A/D conversion time

Hardware trigger wait mode: 2 F<sub>CLK</sub> clocks +A/D power supply stable wait time+A/D conversion

time

(F<sub>CLK</sub>: CPU/peripheral hardware clock frequency)

www.mcu.com.cn 254 / 624 Rev.1.0.3

### Table 11-5: A/D conversion time (1/2)

| 0                  | 1   | 1   | U                                    | F <sub>CLK</sub> /4                          | successive comparison  | -                   |  |
| 1                  | 0   | 0   |                                      | F <sub>CLK</sub> /2                          | clocks).   |                     |  |
| 1                  | 0   | 1   |                                      | Fclk/1                                       |  |                     |  |
| 0                  | 0   | 0   |                                      | F <sub>CLK</sub> /32                         |  | 20/F <sub>AD</sub>  |  |
| 0                  | 0   | 1   |                                      | F <sub>CLK</sub> /16                         | 16 ADCLK   |                     |  |
| 0                  | 1   | 0   | 1                                    | F <sub>CLK</sub> /8                          | (8 sample clocks +12   |                     |  |
| 0                  | 1   | 1   | ı                                    | F <sub>CLK</sub> /4                          | successive comparison  | -                   |  |
| 1                  | 0   | 0   |                                      | F <sub>CLK</sub> /2                          | clocks).   |                     |  |
| 1                  | 0   | 1   |                                      | F <sub>CLK</sub> /1                          |  |                     |  |

Notice: To override the FR2~FR0 bits and ADSMPWAIT bits into different data, it must be done in the conversion stop state (ADCS=0).

Remark: Time required to perform an ADC conversion = (number of sample clocks + number of successive comparison clocks)/F<sub>AD</sub>, where the number of sample clocks can be adjusted via the ADSMPWAIT register, and the default is 4 ADCLKs.The fastest clock supported by ADCLK is 8MHz.

F<sub>CLK</sub>: CPU/peripheral hardware clock frequency

F<sub>AD</sub>: The fastest ADC conversion clock frequency is 8MHz.

| 0   | 1   | 1                | 1  | F <sub>CLK</sub> /4  | Zus                   | 16 successive comparison clocks) |                                     |  |
| 1   | 0   | 0                |  | F <sub>CLK</sub> /2  |                       | oompanoon dooks)                 |                                     |  |
| 1   | 0   | 1                |  | F <sub>CLK</sub> /1  |                       |                                  |                                     |  |

#### Remark:

- 1. In hardware trigger wait mode, the power supply settling time is guaranteed by the hardware design and does not need to be set. And in continuous conversion mode, the A/D power stabilization wait time occurs only after the hardware trigger is detected for the first time.
- Time required for ADC conversion after hardware triggering = 2us + (number of sample clocks + number of successive comparison clocks)/F<sub>AD</sub>. The number of sample clocks can be adjusted via the ADSMPWAIT register, which defaults to four ADCLK. The fastest clock supported by ADCLK is 8MHz.
- 3. To override the FR2~FR0 bits and ADSMPWAIT bits into different data, it must be done in the conversion stop state (ADCS=0).
- 4. The conversion time in the hardware trigger wait mode includes the A/D power stabilization wait time after the hardware trigger is detected.

www.mcu.com.cn 256 / 624 Rev.1.0.3

## 11.2.3 A/D converter mode register 1 (ADM1)

This is the register that sets the A/D conversion mode.

The ADM1 register is set via an 8-bit memory manipulation instruction.

After the reset signal is generated, the value of this register becomes "00H".

Table 11-7: Format of A/D converter mode register 1 (ADM1)

| Reset value: 00H |      | R/W |   |   |       |   |   |   |
|------------------|------|-----|---|---|-------|---|---|---|
|                  | 7    | 6   | 5 | 4 | 3     | 2 | 1 | 0 |
| ADM1             | ADMD | 0   | 0 | 0 | ADSCM | 0 | 0 | 0 |

|   | ADMD | Setting of the A/D conversion channel selection mode |
|---|------|--|
| Ī | 0    | Select mode  |
|   | 1    | Scan mode  |

| ADSCM | Setting of the A/D conversion mode |  |  |  |
|-------|------------------------------------|--|--|--|
| 0     | ontinuous conversion mode          |  |  |  |
| 1     | ingle conversion mode              |  |  |  |

#### Notice:

- 1. Bit 6~4, 2 must be set to "0".
- 2. To override the ADM1 register, it must be done in the conversion stop state (ADCS=0).
- 3. In order to end the A/D conversion normally, the hardware trigger interval must be set at least to the following time:

Hardware trigger no-wait mode: 2 F<sub>CLK</sub> clocks+A/D conversion time

Hardware trigger wait mode: 2 F<sub>CLK</sub> clocks+A/D power supply stable wait time+A/D conversion

#### time

(F<sub>CLK</sub>: CPU/peripheral hardware clock frequency)

www.mcu.com.cn 257 / 624 Rev.1.0.3

### 11.2.4 A/D converter mode register 2 (ADM2)

The ADM2 register is set by an 8-bit memory manipulation instruction.

After the reset signal is generated, the value of this register becomes "00H".

Table 11-8: Format of A/D converter mode register 2 (ADM2)

| Reset v | value: 00H | R/W     |   |   |       |   |       |   |
|---------|------------|---------|---|---|-------|---|-------|---|

|---|--|--|--|--|--|--|
|   | 0  | When ADLL register ≤ ADCR register ≤ ADUL register (AREA1), an interrupt signal (INTAD) is generated.                          |  |  |  |  |
| When ADCR register < ADLL register (AREA2) or ADUL register < ADCR register (AREA2) (INTAD) is generated. |  | When ADCR register < ADLL register (AREA2) or ADUL register < ADCR register (AREA3), an interrupt signal (INTAD) is generated. |  |  |  |  |
| T   | The range of interrupt signal (INTAD) generated from AREA1 to AREA3 is shown in Figure 15-8. |  |  |  |  |  |

| CHRDE | Output enable for channel identification during A/D converter scan mode   |
|-------|---|
| 0     | In scanning mode, the channel number is not identified in the conversion results  |
| 1     | In scanning mode, the high four bits of the converted result ([15:12] of the ADCR register) are the channel numbers for this result |

Figure 11-3: Range of interrupt signal generation for the ADRCK bit

ADCR register value (A/D conversion result)

#### Notice:

- 1. To override the ADM2 register, it must be done in the conversion stop state (ADCS=0).
- 2. When INTAD does not occur, the A/D conversion results are not saved to the ADCR register and the ADCRH register.

www.mcu.com.cn 258 / 624 Rev.1.0.3

### 11.2.5 A/D converter trigger mode register (ADTRG)

This is the register that sets the A/D conversion trigger mode and the hardware trigger signal.

The ADTRG register is set via an 8-bit memory manipulation instruction.

After the reset signal is generated, the value of this register becomes "00H".

Table 11-9: Format of A/D converter trigger mode register (ADTRG)

Reset value: 00H R/W

|       | 7      | 6      | 5 | 4 | 3 | 2 | 1      | 0      |
|-------|--------|--------|---|---|---|---|--------|--------|
| ADTRG | ADTMD1 | ADTMD0 | 0 | 0 | 0 | 0 | ADTRS1 | ADTRS0 |

| ADTMD1 | ADTMD0 | Selection of A/D conversion trigger modes |  |  |
|--------|--------|---|--|--|
| 0      | 0      | Coffugue triangue mode                    |  |  |
| 0      | 1      | Software trigger mode                     |  |  |
| 1      | 0      | ardware trigger no-wait mode              |  |  |
| 1      | 1      | ardware trigger wait mode                 |  |  |

| ADTRS1 | ADTRS0 | Selection of hardware trigger signals   |
|--------|--------|---|
| 0      | 0      | The counting end of timer channel 1 or the capture end of interrupt signal (INTTM01). |
| 0      | 1      | The event signal selected by ELC  |
| 1      | 0      | Real-time clock interrupt signal (INTRTC).  |
| 1      | 1      | Interval timer interrupt signal (INTIT).  |

### Notice:

- 1. To override the ADTRG register, it must be done in the conversion stop state (ADCS=0, ADCE=0).
- 2. In order to end the A/D conversion normally, the hardware trigger interval must be set at least to the following time:

Hardware trigger no-wait mode: 2  $F_{CLK}$  clocks +A/D conversion time

hardware trigger wait mode: 2 F<sub>CLK</sub> clocks +A/D power supply stable wait time +A/D conversion

#### time

(F<sub>CLK</sub>: CPU/peripheral hardware clock frequency)

## 11.2.6 Analog input channel specification register (ADS)

This is the register that specifies the analog voltage input channel for A/D converter.

The ADS register is set by an 8-bit memory manipulation instruction.

After a reset signal is generated, the value of this register becomes "00H".

Table 11-10: Format of analog input channel specification register (ADS)

Reset value: 00H R/W

|     | 7     | 6 | 5    | 4    | 3    | 2    | 1    | 0    |

|       |      | Others: |      |      |        | Settings ar | e disabled. |        |

#### Notice:

- 1. Bit4, bit5 and bit6 must be set to "0" in scan mode.
- 2. For the port set as analog input by PMCx register, it can be designated as analog input for A/D conversion by ADS.
- 3. For pins set as digital input/output by the Port Mode Control Register (PMCxx), they cannot be set by the ADS register.
- 4. To rewrite the ADISS bit, it must be done in the conversion stop state (ADCS=0, ADCE=0).
- 5. After setting the ADISS bit to "1", the result of the first conversion cannot be used.
- 6. The ADISS bit cannot be set to "1" when transferring to deep sleep mode or when transferring to sleep mode while the CPU is running at the sub-system clock.

www.mcu.com.cn 261 / 624 Rev.1.0.3

### 11.2.7 12-bit A/D conversion result register (ADCR)

This is a 16-bit register that stores the A/D conversion result, and this register is read-only. Each time A/D conversion ends, the conversion result is loaded from the successive approximation register (SAR)<sup>Note</sup>.

The high 4 bits of this register are fixed to "0" when the mode is selected, and the channel number of the conversion result can be configured by ADM2.CHRDE=1 in scan mode.

The ADCR register can be read by a 16-bit memory manipulation instruction.

After a reset signal is generated, the value of this register becomes "0000H".

Note: If the value of the A/D conversion result is not within the set value range of the A/D conversion result comparison function (set by the ADRCK bit and the ADUL/ADLL register), the A/D conversion results are not saved.

Table 11-11: Format of 12-bit A/D conversion result register (ADCR)

| Reset  | value. | 0000H  | R  |
|--------|--------|--------|----|
| 1/6961 | value. | 000011 | 1. |

|      | 15    | 14    | 13    | 12    | 11 | 10 | 9 | 8 | 7 | 6    | 5      | 4 | 3 | 2 | 1 | 0 |
|------|-------|-------|-------|-------|----|----|---|---|---|------|--------|---|---|---|---|---|
| ADCR | ADCH3 | ADCH2 | ADCH1 | ADCH0 |    |    |   |   |   | ADCR | [11:0] |   |   |   |   |   |

#### Remark:

- 1. If only 8-bit resolution A/D conversion results are required, the higher 8 bits of the conversion result can be read by the ADCRH register.
- 2. When 16 bits of access are made to the ADCR register, the higher 12 bits of the conversion result can be read sequentially from bit11.
- Select mode (ADM1.ADMD=0)

The readout value of ADCH0~3 is fixed at 4 'b0000

• Scan mode (ADM1.ADMD=1) and ADM2.CHRDE=1, the relationship between the readout values of ADCH0~3 and the converted channels is as follows

| ADCH3 | ADCH2 | ADCH1 | ADCH0 | Conversion channel ID |
|-------|-------|-------|-------|-----------------------|
| 0     | 0     | 0     | 0     | ANI0                  |
| 0     | 0     | 0     | 1     | ANI1                  |
| 0     | 0     | 1     | 0     | ANI2                  |
| 0     | 0     | 1     | 1     | ANI3                  |
| 0     | 1     | 0     | 0     | ANI4                  |
| 0     | 1     | 0     | 1     | ANI5                  |

| 1     | 1     | 1     | 0     | ANI14                 |
| 1     | 1     | 1     | 1     | ANI15                 |

www.mcu.com.cn 262 / 624 Rev.1.0.3

### 11.2.8 8-bit A/D conversion result register (ADCRH)

This register is an 8-bit register that stores the A/D conversion result. The higher 8 bits of 12-bit resolution are stored<sup>Note</sup>.

The ADCRH register can be read by an 8-bit memory manipulation instruction.

After a reset signal is generated, the value of this register becomes "00H".

Note: If the value of the A/D conversion result is not within the set value range of the A/D conversion result comparison function (set by the ADRCK bit and the ADUL/ADLL register), the A/D conversion results are not saved.

Table 11-12: Format of 8-bit A/D conversion result register (ADCRH)

| Reset va | lue: 00H R |   |   |   |   |   |   |   |
|----------|------------|---|---|---|---|---|---|---|
|          | 7          | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| ADCRH    |            |   |   |   |   |   |   |   |

Notice: Read the conversion result following conversion completion before writing to the ADM0, ADS registers. Otherwise, you may not read the correct conversion results.

## 11.2.9 Conversion result comparison upper limit setting register (ADUL)

This register is used to specify the setting for checking the upper limit of the A/D conversion results. The A/D conversion results and ADUL register value are compared, and interrupt signal (INTAD) generation is controlled in the range specified by the ADRCK bit of A/D converter mode register 2 (ADM2) (shown in Figure 11-3: Range of interrupt signal generation for the ADRCK bit). The ADUL register is set by an 8-bit memory manipulation instruction.

After a reset signal is generated, the value of this register becomes "FFH".

- Note 1: Only the higher 8 bits of the 12-bit A/D conversion result register (ADCR) are compared with the ADUL register and the ADLL register.
- Note 2: Rewrite the value of the ADUL register and ADLL register while conversion is stopped (ADCS = 0).

Note 3: Rewrite the value of the ADUL register and ADLL register while ADUL>ADLL.

Table 11-13: Format of conversion result comparison upper limit setting register (ADUL) Reset value: FFH R/W

|      | 7     | 6     | 5     | 4     | 3     | 2     | 1     | 0     |
|------|-------|-------|-------|-------|-------|-------|-------|-------|
| ADUL | ADUL7 | ADUL6 | ADUL5 | ADUL4 | ADUL3 | ADUL2 | ADUL1 | ADUL0 |

## 11.2.10 Conversion result comparison lower limit setting register (ADLL)

This register is used to specify the setting for checking the lower limit of the A/D conversion results.

The A/D conversion results and ADLL register value are compared, and interrupt signal (INTAD) generation is controlled in the range specified by the ADRCK bit of A/D converter mode register 2 (ADM2) (shown in Figure 11-3: Range of interrupt signal generation for the ADRCK bit).

The ADLL register is set by an 8-bit memory manipulation instruction.

After a reset signal is generated, the value of this register becomes "00H".

Table 11-14: Format of conversion result comparison lower limit setting register (ADLL)

Reset value: 00H R/W

|      | 7     | 6     | 5     | 4     | 3     | 2     | 1     | 0     |
|------|-------|-------|-------|-------|-------|-------|-------|-------|
| ADLL | ADLL7 | ADLL6 | ADLL5 | ADLL4 | ADLL3 | ADLL2 | ADLL1 | ADLL0 |

#### Notice:

- 1. Only the higher 8 bits of the 12-bit A/D conversion result register (ADCR) are compared with the ADUL register and the ADLL register.
- 2. Rewrite the value of the ADUL register and ADLL register while conversion is stopped (ADCS = 0).
- 3. Rewrite the value of the ADUL register and ADLL register while ADUL>ADLL.

### 11.2.11 A/D converter sampling time control register (ADNSMP)

This register controls the A/D sampling time.

The ADNSMP register is set by an 8-bit memory manipulation instruction.

After a reset signal is generated, the value of this register becomes "00H".

Table 11-15: Format of A/D converter sampling time control register (ADNSMP)

Reset value: 00H R/W

|           | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0         |
|-----------|---|---|---|---|---|---|---|-----------|
| ADSMPWAIT | 0 | 0 | 0 | 0 | 0 | 0 | 0 | ADSMPWAIT |

| ADSMPWAIT | A/D conversion target                              |
|-----------|--|
| 0         | When it is "0", the A/D sampling time is 4 ADCLKs. |
| 1         | When it is "1", the A/D sampling time is 8 ADCLKs. |

Remark: Set ADSMPWAIT in the conversion stop state (ADCS=0).

### 11.2.12 Registers for controlling analog input port function

When using the ANIx pin as the analog input to an A/D converter, the port must be configured as an analog channel by setting the corresponding Port Mode Control Register (PMCxx) bit to "1". For details, please refer to "Chapter 2 Port Function".

## 11.3 Input voltage and conversion results

The analog input voltage at the analog input pin (ANIx) and the theoretical A/D conversion result (12-bit A/D Conversion Result Register (ADCR)) are related by the following expressions.

$$ADCR = INT(\frac{V_{AIN}}{AV_{REF}} \times 4096 + 0.5) \text{ or } (ADCR - 0.5) \times \frac{AV_{REF}}{4096} \leqslant V_{AIN} < (ADCR + 0.5) \times \frac{AV_{REF}}{4096} = 0.5$$

INT(): A function that returns the integer portion of a numeric value in parentheses

V<sub>AIN</sub>: Analog input voltage AV<sub>REF</sub>: AV<sub>REF</sub> pin voltage

ADCR: The value of the A/D conversion result register (ADCR)

SAR: Successive approximation register

The relationship between the analog input voltage and the A/D conversion results is shown in the following figure.

Figure 11-4: Analog input voltage vs. A/D conversion results

A/D conversion result

Input voltage/AV<sub>REF</sub>

Remark: AV<sub>REF</sub> is the positive (+) reference voltage of the A/D converter.

## 11.4 Operation mode of A/D converter

The A/D converter conversion operations are described below. For the setting of each mode, please refer to "11.5 A/D converter setup flowchart".

## 11.4.1 Software trigger mode (select mode, sequential conversion mode)

- ① In the stop state, enter A/D conversion standby state by setting the ADCE bit of the A/D converter mode register 0 (ADM0) to "1".
- ② After the software counts up to the stabilization wait time (1 μs), the ADCS bit of the ADM0 register is set to 1 to perform the A/D conversion of the analog input specified by the analog input channel specification register (ADS).
- When A/D conversion ends, the conversion result is stored in the A/D conversion result register (ADCR, ADCRH), and the A/D conversion end interrupt request signal (INTAD) is generated. After A/D conversion ends, the next A/D conversion immediately starts.
- When ADCS is overwritten with 1 during conversion operation, the current A/D conversion is interrupted, and conversion restarts.
- (5) When the value of the ADS register is rewritten or overwritten during conversion operation, the current A/D conversion is interrupted, and A/D conversion is performed on the analog input respecified by the ADS register.
- 6 Even if a hardware trigger is input during conversion operation, A/D conversion does not start.
- When ADCS is cleared to 0 during conversion operation, the current A/D conversion is interrupted, and the system enters the A/D conversion standby status.
- When ADCE is cleared to 0 while in the A/D conversion standby status, the A/D converter enters the stop status. When ADCE = 0, specifying 1 for ADCS is ignored and A/D conversion does not start.

Figure 11-5: Example of software trigger mode (select mode, sequential conversion mode) operation timing

www.mcu.com.cn 266 / 624 Rev.1.0.3

### 11.4.2 Software trigger mode (select mode, single conversion mode)

- ① In the stop state, enter A/D conversion standby state by setting the ADCE bit of the A/D converter mode register 0 (ADM0) to "1".
- ② After the software counts up to the stabilization wait time (1 μs), the ADCS bit of the ADM0 register is set to 1 to perform the A/D conversion of the analog input specified by the analog input channel specification register (ADS).
- ③ When A/D conversion ends, the conversion result is stored in the A/D conversion result register (ADCR, ADCRH), and the A/D conversion end interrupt request signal (INTAD) is generated.
- ④ After A/D conversion ends, the ADCS bit is automatically cleared to "0", and the system enters the A/D conversion standby status.
- (5) When ADCS is overwritten with 1 during conversion operation, the current A/D conversion is interrupted, and conversion restarts.
- 6 When the value of the ADS register is rewritten or overwritten during conversion operation, the current A/D conversion is interrupted, and A/D conversion is performed on the analog input respecified by the ADS register.
- When ADCS is cleared to 0 during conversion operation, the current A/D conversion is interrupted, and the system enters the A/D conversion standby status.
- When ADCE is cleared to 0 while in the A/D conversion standby status, the A/D converter enters the stop status. When ADCE = 0, specifying 1 for ADCS is ignored and A/D conversion does not start. In addition, A/D conversion does not start even if a hardware trigger is input while in the A/D conversion standby status.

Figure 11-6: Example of software trigger mode (select mode, single conversion mode) operation timing

www.mcu.com.cn 267 / 624 Rev.1.0.3

## 11.4.3 Software trigger mode (scan mode, sequential conversion mode)

- ① In the stop state, enter A/D conversion standby state by setting the ADCE bit of the A/D converter mode register 0 (ADM0) to "1".
- ② After the software counts up to the stabilization wait time (1 μs), the ADCS bit of the ADM0 register is set to 1 to perform A/D conversion on the four analog input channels specified by scan 0 to scan 3, which are specified by the analog input channel specification register (ADS). A/D conversion is performed on the analog input channels in order, starting with that specified by scan 0.
- ③ A/D conversion is sequentially performed on the four analog input channels. When A/D conversion ends, the conversion result is stored in the A/D conversion result register (ADCR, ADCRH), and the A/D conversion end interrupt request signal (INTAD) is generated. After A/D conversion of the four channels ends, the A/D conversion of the channel following the specified channel automatically starts (until all four channels are finished).
- When ADCS is overwritten with "1" during conversion operation, the current A/D conversion is interrupted, and conversion restarts.
- (5) When the value of the ADS register is rewritten or overwritten during conversion operation, the current A/D conversion is interrupted, and A/D conversion is performed on the first channel respecified by the ADS register.
- 6 Even if a hardware trigger is input during conversion operation, A/D conversion does not start.
- When ADCS is cleared to 0 during conversion operation, the current A/D conversion is interrupted, and the system enters the A/D conversion standby status.
- When ADCE is cleared to 0 while in the A/D conversion standby status, the A/D converter enters the stop status. When ADCE = 0, specifying 1 for ADCS is ignored and A/D conversion does not start.

Figure 11-7: Example of software trigger mode (scan mode, sequential conversion mode) operation timin

www.mcu.com.cn 268 / 624 Rev.1.0.3

### 11.4.4 Software trigger mode (scan mode, single conversion mode)

- ① In the stop state, enter A/D conversion standby state by setting the ADCE bit of the A/D converter mode register 0 (ADM0) to "1".
- ② After the software counts up to the stabilization wait time (1 μs), the ADCS bit of the ADM0 register is set to 1 to perform A/D conversion on the four analog input channels specified by scan 0 to scan 3, which are specified by the analog input channel specification register (ADS). A/D conversion is performed on the analog input channels in order, starting with that specified by scan 0.
- ③ A/D conversion is sequentially performed on the four analog input channels. When A/D conversion ends, the conversion result is stored in the A/D conversion result register (ADCR, ADCRH), and the A/D conversion end interrupt request signal (INTAD) is generated.
- 4 After A/D conversion of the four channels ends, the ADCS bit is automatically cleared to 0, and the system enters the A/D conversion standby status.
- (5) When ADCS is overwritten with "1" during conversion operation, the current A/D conversion is interrupted, and conversion restarts.
- 6 When the value of the ADS register is rewritten or overwritten during conversion operation, the current A/D conversion is interrupted, and A/D conversion is performed on the first channel respecified by the ADS register.
- When ADCS is cleared to 0 during conversion operation, the current A/D conversion is interrupted, and the system enters the A/D conversion standby status.
- When ADCE is cleared to 0 while in the A/D conversion standby status, the A/D converter enters the stop status. When ADCE = 0, specifying 1 for ADCS is ignored and A/D conversion does not start. In addition, A/D conversion does not start even if a hardware trigger is input while in the A/D conversion standby status.

Figure 11-8: Example of software trigger mode (scan mode, single conversion mode) operation timing

www.mcu.com.cn 269 / 624 Rev.1.0.3

## 11.4.5 Hardware trigger no-wait mode (select mode, sequential conversion mode)

- ① In the stop state, enter A/D conversion standby state by setting the ADCE bit of the A/D converter mode register 0 (ADM0) to "1".
- ② After the software counts up to the stabilization wait time (1 μs), the ADCS bit of the ADM0 register is set to 1 to place the system in the hardware trigger standby status (and conversion does not start at this stage). Note that, while in this status, A/D conversion does not start even if ADCS is set to 1.
- ③ If a hardware trigger is input while ADCS = 1, A/D conversion is performed on the analog input specified by the analog input channel specification register (ADS).
- When A/D conversion ends, the conversion result is stored in the A/D conversion result register (ADCR, ADCRH), and the A/D conversion end interrupt request signal (INTAD) is generated. After A/D conversion ends, the next A/D conversion immediately starts.
- ⑤ If a hardware trigger is input during conversion operation, the current A/D conversion is interrupted, and conversion restarts.
- When the value of the ADS register is rewritten or overwritten during conversion operation, the current A/D conversion is interrupted, and A/D conversion is performed on the analog input respecified by the ADS register.
- When ADCS is overwritten with 1 during conversion operation, the current A/D conversion is interrupted, and conversion restarts.
- When ADCS is cleared to 0 during conversion operation, the current A/D conversion is interrupted, and the system enters the A/D conversion standby status. However, the A/D converter does not stop in this status.
- When ADCE is cleared to 0 while in the A/D conversion standby status, the A/D converter enters the stop status. When ADCS = 0, inputting a hardware trigger is ignored and A/D conversion does not start.

Figure 11-9: Example of hardware trigger no-wait mode (select mode, sequential conversion mode) operation timing

www.mcu.com.cn 270 / 624 Rev.1.0.3

## 11.4.6 Hardware trigger no-wait mode (select mode, single conversion mode)

- ① In the stop state, enter A/D conversion standby state by setting the ADCE bit of the A/D converter mode register 0 (ADM0) to "1".
- ② After the software counts up to the stabilization wait time (1 μs), the ADCS bit of the ADM0 register is set to 1 to place the system in the hardware trigger standby status (and conversion does not start at this stage). Note that, while in this status, A/D conversion does not start even if ADCS is set to 1.
- ③ If a hardware trigger is input while ADCS = 1, A/D conversion is performed on the analog input specified by the analog input channel specification register (ADS).
- When A/D conversion ends, the conversion result is stored in the A/D conversion result register (ADCR, ADCRH), and the A/D conversion end interrupt request signal (INTAD) is generated.
- (5) After A/D conversion ends, the ADCS bit remains set to "1", and the system enters the A/D conversion standby status.
- 6 If a hardware trigger is input during conversion operation, the current A/D conversion is interrupted, and conversion restarts.
- When the value of the ADS register is rewritten or overwritten during conversion operation, the current A/D conversion is interrupted, and A/D conversion is performed on the analog input respecified by the ADS register.
- When ADCS is overwritten with 1 during conversion operation, the current A/D conversion is interrupted, and conversion restarts.
- When ADCS is cleared to 0 during conversion operation, the current A/D conversion is interrupted, and the system enters the A/D conversion standby status. However, the A/D converter does not stop in this status.
- When ADCE is cleared to 0 while in the A/D conversion standby status, the A/D converter enters the stop status. When ADCS = 0, inputting a hardware trigger is ignored and A/D conversion does not start.

Figure 11-10: Example of hardware trigger no-wait mode (select mode, single conversion mode) operation timing

www.mcu.com.cn 271 / 624 Rev.1.0.3

## 11.4.7 Hardware trigger no-wait mode (scan mode, sequential conversion mode)

- ① In the stop state, enter A/D conversion standby state by setting the ADCE bit of the A/D converter mode register 0 (ADM0) to "1".
- ② After the software counts up to the stabilization wait time (1 μs), the ADCS bit of the ADM0 register is set to 1 to place the system in the hardware trigger standby status (and conversion does not start at this stage). Note that, while in this status, A/D conversion does not start even if ADCS is set to 1.
- If a hardware trigger is input while ADCS = 1, A/D conversion is performed on the four analog input channels specified by scan 0 to scan 3, which are specified by the analog input channel specification register (ADS). A/D conversion is performed on the analog input channels in order, starting with that specified by scan 0.
- 4 A/D conversion is sequentially performed on the four analog input channels. When A/D conversion ends, the conversion result is stored in the A/D conversion result register (ADCR, ADCRH), and the A/D conversion end interrupt request signal (INTAD) is generated. After A/D conversion of the four channels ends, the A/D conversion of the channel following the specified channel automatically starts.
- (5) If a hardware trigger is input during conversion operation, the current A/D conversion is interrupted, and conversion restarts at the first channel.
- When the value of the ADS register is rewritten or overwritten during conversion operation, the current A/D conversion is interrupted, and A/D conversion is performed on the channel respecified by the ADS register.
- When ADCS is overwritten with 1 during conversion operation, the current A/D conversion is interrupted, and conversion restarts at the first channel.
- When ADCS is cleared to 0 during conversion operation, the current A/D conversion is interrupted, and the system enters the A/D conversion standby status. However, the A/D converter does not stop in this status.
- When ADCE is cleared to 0 while in the A/D conversion standby status, the A/D converter enters the stop status. When ADCE = 0, specifying 1 for ADCS is ignored and A/D conversion does not start.

Figure 11-11: Example of hardware trigger no-wait mode (scan mode, sequential conversion mode)

www.mcu.com.cn 272 / 624 Rev.1.0.3

## 11.4.8 Hardware trigger no-wait mode (scan mode, single conversion mode)

- ① In the stop state, enter A/D conversion standby state by setting the ADCE bit of the A/D converter mode register 0 (ADM0) to "1".
- ② After the software counts up to the stabilization wait time (1 μs), the ADCS bit of the ADM0 register is set to 1 to place the system in the hardware trigger standby status (and conversion does not start at this stage). Note that, while in this status, A/D conversion does not start even if ADCS is set to 1.
- ③ If a hardware trigger is input while ADCS = 1, A/D conversion is performed on the four analog input channels specified by scan 0 to scan 3, which are specified by the analog input channel specification register (ADS). A/D conversion is performed on the analog input channels in order, starting with that specified by scan 0.
- 4 A/D conversion is sequentially performed on the four analog input channels. When A/D conversion ends, the conversion result is stored in the A/D conversion result register (ADCR, ADCRH), and the A/D conversion end interrupt request signal (INTAD) is generated.
- ⑤ After A/D conversion of the four channels ends, the ADCS bit remains set to "1", and the system enters the A/D conversion standby status.
- 6 If a hardware trigger is input during conversion operation, the current A/D conversion is interrupted, and conversion restarts at the first channel.
- When the value of the ADS register is rewritten or overwritten during conversion operation, the current A/D conversion is interrupted, and A/D conversion is performed on the first channel respecified by the ADS register.
- When ADCS is overwritten with 1 during conversion operation, the current A/D conversion is interrupted, and conversion restarts at the first channel.
- When ADCS is cleared to 0 during conversion operation, the current A/D conversion is interrupted, and the system enters the A/D conversion standby status. However, the A/D converter does not stop in this status.
- When ADCE is cleared to 0 while in the A/D conversion standby status, the A/D converter enters the stop status. When ADCS = 0, inputting a hardware trigger is ignored and A/D conversion does not start.

www.mcu.com.cn 273 / 624 Rev.1.0.3

## 11.4.9 Hardware trigger wait mode (select mode, sequential conversion mode)

- ① In the stop status, the ADCE bit of A/D converter mode register 0 (ADM0) is set to 1, and the system enters the hardware trigger standby status.
- ② If a hardware trigger is input while in the hardware trigger standby status, A/D conversion is performed on the analog input specified by the analog input channel specification register (ADS). The ADCS bit of the ADM0 register is automatically set to 1 according to the hardware trigger input.
- When A/D conversion ends, the conversion result is stored in the A/D conversion result register (ADCR, ADCRH), and the A/D conversion end interrupt request signal (INTAD) is generated. After A/D conversion ends, the next A/D conversion immediately starts. (At this time, no hardware trigger is necessary.)
- ④ If a hardware trigger is input during conversion operation, the current A/D conversion is interrupted, and conversion restarts.
- (5) When the value of the ADS register is rewritten or overwritten during conversion operation, the current A/D conversion is interrupted, and A/D conversion is performed on the analog input respecified by the ADS register.
- 6 When ADCS is overwritten with 1 during conversion operation, the current A/D conversion is interrupted, and conversion restarts.
- When ADCS is cleared to 0 during conversion operation, the current A/D conversion is interrupted, the system enters the hardware trigger standby status, and the A/D converter enters the stop status. When ADCE = 0, inputting a hardware trigger is ignored and A/D conversion does not start.

Figure 11-13: Example of hardware trigger wait mode (select mode, sequential conversion mode) operation timing

www.mcu.com.cn 274 / 624 Rev.1.0.3

## 11.4.10 Hardware trigger wait mode (select mode, single conversion mode)

- ① In the stop status, the ADCE bit of A/D converter mode register 0 (ADM0) is set to 1, and the system enters the hardware trigger standby status.
- ② If a hardware trigger is input while in the hardware trigger standby status, A/D conversion is performed on the analog input specified by the analog input channel specification register (ADS). The ADCS bit of the ADM0 register is automatically set to 1 according to the hardware trigger input.
- ③ When A/D conversion ends, the conversion result is stored in the A/D conversion result register (ADCR, ADCRH), and the A/D conversion end interrupt request signal (INTAD) is generated.
- After A/D conversion ends, the ADCS bit is automatically cleared to 0, and the A/D converter enters the stop status.
- ⑤ If a hardware trigger is input during conversion operation, the current A/D conversion is interrupted, and conversion restarts.
- When the value of the ADS register is rewritten or overwritten during conversion operation, the current A/D conversion is interrupted, and A/D conversion is performed on the analog input respecified by the ADS register.
- When ADCS is overwritten with 1 during conversion operation, the current A/D conversion is interrupted, and conversion restarts.
- When ADCS is cleared to 0 during conversion operation, the current A/D conversion is interrupted, the system enters the hardware trigger standby status, and the A/D converter enters the stop status. When ADCE = 0, inputting a hardware trigger is ignored and A/D conversion does not start.

Figure 11-14: Example of hardware trigger wait mode (select mode, single conversion mode) operation timing

www.mcu.com.cn 275 / 624 Rev.1.0.3

## 11.4.11 Hardware trigger wait mode (scan mode, sequential conversion mode)

- ① In the stop status, the ADCE bit of A/D converter mode register 0 (ADM0) is set to 1, and the system enters the hardware trigger standby status.
- ② If a hardware trigger is input while in the hardware trigger standby status, A/D conversion is performed on the four analog input channels specified by scan 0 to scan 3, which are specified by the analog input channel specification register (ADS). The ADCS bit of the ADM0 register is automatically set to 1 according to the hardware trigger input. A/D conversion is performed on the analog input channels in order, starting with that specified by scan 0.
- ③ A/D conversion is sequentially performed on the four analog input channels. When A/D conversion ends, the conversion result is stored in the A/D conversion result register (ADCR, ADCRH), and the A/D conversion end interrupt request signal (INTAD) is generated. After A/D conversion of the four channels ends, the A/D conversion of the channel following the specified channel automatically starts.
- ④ If a hardware trigger is input during conversion operation, the current A/D conversion is interrupted, and conversion restarts at the first channel.
- When the value of the ADS register is rewritten or overwritten during conversion operation, the current A/D conversion is interrupted, and A/D conversion is performed on the channel respecified by the ADS register.
- 6 When ADCS is overwritten with 1 during conversion operation, the current A/D conversion is interrupted, and conversion restarts at the first channel.
- When ADCS is cleared to 0 during conversion operation, the current A/D conversion is interrupted, the system enters the hardware trigger standby status, and the A/D converter enters the stop status. When ADCE = 0, inputting a hardware trigger is ignored and A/D conversion does not start.

Figure 11-15: Example of hardware trigger wait mode (scan mode, sequential conversion mode) operation timing

www.mcu.com.cn 276 / 624 Rev.1.0.3

## 11.4.12 Hardware trigger wait mode (scan mode, single conversion mode)

- ① In the stop status, the ADCE bit of A/D converter mode register 0 (ADM0) is set to 1, and the system enters the hardware trigger standby status.
- ② If a hardware trigger is input while in the hardware trigger standby status, A/D conversion is performed on the four analog input channels specified by scan 0 to scan 3, which are specified by the analog input channel specification register (ADS). The ADCS bit of the ADM0 register is automatically set to 1 according to the hardware trigger input. A/D conversion is performed on the analog input channels in order, starting with that specified by scan 0.
- 3 A/D conversion is sequentially performed on the four analog input channels. When A/D conversion ends, the conversion result is stored in the A/D conversion result register (ADCR, ADCRH), and the A/D conversion end interrupt request signal (INTAD) is generated.
- ④ After A/D conversion ends, the ADCS bit is automatically cleared to 0, and the A/D converter enters the stop status.
- ⑤ If a hardware trigger is input during conversion operation, the current A/D conversion is interrupted, and scan conversion restarts at the first channel.
- When the value of the ADS register is rewritten or overwritten during conversion operation, the current A/D conversion is interrupted, and scan conversion is performed on the channel respecified by the ADS register.
- When ADCS is overwritten with 1 during conversion operation, the current A/D conversion is interrupted, and scan conversion restarts at the first channel.
- When ADCS is cleared to 0 during conversion operation, the current A/D conversion is interrupted, the system enters the hardware trigger standby status, and the A/D converter enters the stop status. When ADCE = 0, inputting a hardware trigger is ignored and A/D conversion does not start.

A/D conversion in based on ADRCK bit and ADUL/ADLL register configuration, progress compare with result of A/D conversion, hardware will A/D conversion in progress automatically decide whether to generate A/D conversion completion interrupt (INTAD). the conversion result will if A/D conversion interrupt (INTAD) is generated, the conversion result will be saved into ADCR register. Otherwise, be saved into ADCR

the conversion result will not be saved into ADCR register.

# Chapter 12 General-Purpose Serial Communication Unit

This product is equipped with 2 general-purpose serial communication units, each unit has 2 serial channels, each channel can realize 3-wire serial (SSPI), UART communication. Function assignment of each channel supported by this product is as shown below.

Table 12-1: Function assignment of general-purpose serial communication unit

| Unit | Channel | Used as SSPI | Used as UART             |  |  |  |  |
|------|---------|--------------|--------------------------|--|--|--|--|
| 0    | 0       | SSPI00       | UART0 (supports LIN-bus) |  |  |  |  |
|      | 1       | SSPI01       | OAKTO (supports Lin-bus) |  |  |  |  |
| 1    | 0       | SSPI10       | LIADT4                   |  |  |  |  |
|      | 1       | SSPI11       | UART1                    |  |  |  |  |

#### Notice:

- 1. "-" indicates that it is not supported in this model;
- 2. When "UART0" is used for channels 0 and 1 of the unit 0, SSPI00, SSPI01, IIC00 and IIC01 cannot be used.
- 3. When "UART1" is used for channels 0 and 1 of the unit 1, SSPI10, SSPI11, IIC10 and IIC11 cannot be used.

www.mcu.com.cn 281 / 624 Rev.1.0.3

### 12.1 Function of general-purpose serial communication unit

Each serial interface supported by this product has the following features.

### 12.1.1 3-wire serial I/O (SSPI00, SSPI01, SSPI10, SSPI11)

Synchronizes with the serial clock (SCLK) output from the master device for data transmission and reception.

This is a clock-synchronous communication function that uses a serial clock (SCLK), a transmit serial data (SDO), and a receive serial data (SDI) for communication on a total of three communication lines.

For specific setting examples, please refer to "12.1.1 Operation of 3-wire serial I/O (SSPI00, SSPI01, SSPI10, SSPI11) communication".

[Data transmission and reception]

Data length of 7~16 bits

Phase control of transmit/receive data

MSB/LSB preferred option

Level setting for transmit/receive data

#### [Clock Control]

- (1) Master/slave selection
- (2) Phase control of I/O clock
- (3) Setting of transfer period by prescaler and internal counter
- (4) Maximum transfer rate

During master communication: Max.F<sub>CLK</sub>/2 During slave communication: Max.F<sub>MCK</sub>/6

[Interrupt function]

Transfer end interrupt, buffer empty interrupt

[Error detection flag]

Overflow error

Notice: Use the clocks within a range satisfying the SCLK cycle time ( $T_{KCY}$ ) characteristics. For details, please refer to the data sheet.

### 12.1.2 UART (UARTO, UART1)

This is an asynchronous function using two lines: serial data transmission (TxD) and serial data reception (RxD) lines. By using these two communication lines, data is sent and received asynchronously (using the internal baud rate) with other communicating parties by data frame (consisting of start bits, data, parity bits, and stop bits). Full-duplex UART communication can be performed by using a channel dedicated to transmission (even-numbered channel 00) and a channel dedicated to reception (odd-numbered channel 01).

For details about the settings, please refer to "12.7 Operation of UART (UART0~UART1)".

[Data transmission and reception]

- (1) Data length of 7, 8, 9 or 16 bits
- (2) MSB/LSB preferred option
- (3) Level setting of transmit/receive data and select of reverse
- (4) Parity bit appending and parity check functions
- (5) Stop bit appending

[Interrupt function]

- (1) Transfer end interrupt, buffer empty interrupt
- (2) Error interrupt in case of framing error, parity error, or overflow error

[Error detection flag]

Framing error, parity error, or overflow error

### 12.2.1 Shift register

This is a 16-bit register that converts parallel data into serial data or vice versa.

During reception, it converts data input to the serial pin into parallel data. When data is transmitted, the value set to this register is output as serial data from the serial output pin. The shift register cannot be directly manipulated by program.

To read or write the shift register, use the serial data register mn (SDRmn) when operation is in progress (SEmn = 1).

| Table | 12-3: | Format | of shift | register |
|-------|-------|--------|----------|----------|
|       |       |        |          |          |

|          | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----------|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| Shift    |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
| register |    |    |    |    |    |    |   |   |   |   |   |   |   |   |   |   |

### 12.2.2 Serial data register mn (SDRmn)

The SDRmn register is the transmit/receive data register (16 bits) of channel n.

If operation is stopped (SEmn = 0), bits 15 to 9 are used as a register that sets the division ratio of the operation clock ( $F_{MCK}$ ). If operation is in progress (SEmn = 1), bit15~9 selected as a transmit/receive buffer register.

When receiving data, the parallel data converted by the shift register is saved to the serial data register SDRmn; when sending data, the send data that is transferred to the shift register is set to the serial data register SDRmn.

Regardless of the output order of the data, the data saved to the SDRmn register according to the setting of bit3 to bit0 (DLSmn3 to DLSmn0) of the serial communication run setting register mn (SCRmn) is shown below:

- (1) 7-bit data length (stored in bit0~6 of SDRmn register)
- (2) 8-bit data length (stored in bit0~7 of SDRmn register)
- (3) 16-bit data length (stored in bit0~15 of SDRmn register)

The SDRmn register can be read or written in 16-bit units.

When SEmn=1, the lower 8 bits of the SDRmn register can be read and written in 8-bit increments as SDRmnL<sup>Note</sup>.

According to the communication mode, it can read and write SDRmnL registers with the following SFR names.

- (1) SSPIp communication.....SDIOpL
- (2) UARTq reception.....RXDq (UARTq receive data register)
- (3) UARTq transmission.....TXDq (UARTq transmit data register)

After the reset signal is generated, the value of SDRmn register changes to "0000H".

Note: At run stop (SEmn=0), it is forbidden to rewrite SDRmn[7:0] by 8-bit memory manipulation instruction (otherwise, all of SDRmn[15:9] will be cleared to "0").

Remark: unit number (m=0, 1);

n: channel number (n=0, 1);

p: SSPI number (p=00, 01, 10, 11);

q: UART number (q=0, 1);

Table 12-4: Format of serial data register mn (SDRmn)

R/W After reset: 0000H 15 14 13 12 11 10 9 8 6 **SDRmn** 15 14 13 12 11 10 9 6 5 2 0 Shift register

#### Remark:

- 1. For the function of the higher 7 bits of the SDRmn register, please refer to "12.3 Registers for controlling general-purpose serial communication unit";
- 2. m: unit number (m=0, 1);n: channel number (n=0, 1).

| 0x042          | SDRm1         | R/W | 0000H       |

Remark: unit number m=0, 1.

## 12.3.1 Peripheral enable register 0 (PER0)

The PER0 register is the register that sets whether to enable or disable the supply of clocks to each peripheral hardware. Reduce power consumption and noise by stopping clocks to hardware that is not in use.

To use general-purpose serial communication unit 0, bit 2 (SCI0EN) must be set to "1".

To use general-purpose serial communication unit 1, bit 3 (SCI1EN) must be set to "1".

The PER0 register is set by an 8-bit memory manipulation instruction.

After a reset signal is generated, the value of the PER0 register changes to "00H".

Table 12-6: Format of peripheral enabled register 0 (PER0)

| Address: 0x40020420 |       | After res | et: 00H |        | R/W    | R/W    |        |        |  |  |
|---------------------|-------|-----------|---------|--------|--------|--------|--------|--------|--|--|
| Symbol              | 7     | 6         | 5       | 4      | 3      | 2      | 1      | 0      |  |  |
| PER0                | RTCEN | 0         | ADCEN   | IICAEN | SCI1EN | SCI0EN | TM41EN | TM40EN |  |  |

| _ |        |   |
|---|--------|---|
|   | SCImEN | Provides control of the input clock of general-purpose serial communication unit m  |
|   | 0      | Stop to supply the input clock. The SFR used by the general-purpose serial communication unit m cannot be written. The general-purpose serial communication unit m is in the reset state. |
|   | 1      | Enable the input clock to be provided. Can read and write the SFR used by the general-purpose serial communication unit m.  |

Notice: To set the Universal Serial Communication Unit m, the following registers must be set in the state of SCImEN bit "1" first. When the SCImEN bit is "0", the write operation of the control registers of the Universal Serial Communication Unit m is ignored, and the read values are all initial values (input switching control register (ISC), noise filter allow register 0 (NFEN0), port multiplex function configuration register (PxxCFG), port output mode register (POMx), port mode register (PMx), and port mode register (PMx). Mode Register (POMx), Port Mode Register (PMx), Port Mode Control Register (PMCx), and Port Register (Px) are excluded).

- (1) Serial clock select register m (SPSm)
- (2) Serial mode register mn (SMRmn)
- (3) Serial communication run setting registermn (SCRmn)
- (4) Serial data register mn (SDRmn)
- (5) Serial flag clear trigger register mn (SIRmn)
- (6) Serial status register mn (SSRmn)
- (7) Serial channel start register m (SSm)
- (8) Serial channel stop register m (STm)
- (9) Serial channel enable status register m (SEm)
- (10) Serial output enable register m (SOEm)
- (11) Serial output level register m (SOLm)
- (12) Serial output register m (SOm)

## 12.3.2 Serial clock select register m (SPSm)

The SPSm register is a 16-bit register that selects two common operating clocks (CKm0, CKm1) available to each channel. Select CKm1 by bit7 to 4 of the SPSm register and select from bit3 to 0 CKm0.

It is forbidden to overwrite the SPSm register during operation (SEmn=1).

The SPSm register is set by a 16-bit memory manipulation instruction.

It can set the low 8 bits of the SPSm register with SPSmL and through the 8-bit memory manipulation instruction.

After generating a reset signal, the value of the SPSm register changes to "0000H".

Table 12-7: Format of serial clock selection register m (SPSm)

| After reset: |    |    |    | 000 | 0000H |    |   |   |      |      |      | R/W  |      |      |      |      |  |
|--------------|----|----|----|-----|-------|----|---|---|------|------|------|------|------|------|------|------|--|

| PRSmk3 | PRSmk2 | PRSmk1 | PRSmk0 | Operation clock (CKmk) selection <sup>Note</sup> |
|--------|--------|--------|--------|--|
| 0      | 0      | 0      | 0      | Fclk   |
| 0      | 0      | 0      | 1      | F <sub>CLK</sub> /2                              |
| 0      | 0      | 1      | 0      | F <sub>CLK</sub> /2 <sup>2</sup>                 |
| 0      | 0      | 1      | 1      | F <sub>CLK</sub> /2 <sup>3</sup>                 |
| 0      | 1      | 0      | 0      | Fclk/2 <sup>4</sup>                              |
| 0      | 1      | 0      | 1      | Fclk/2 <sup>5</sup>                              |
| 0      | 1      | 1      | 0      | Fclк/2 <sup>6</sup>                              |
| 0      | 1      | 1      | 1      | Fclk/2 <sup>7</sup>                              |
| 1      | 0      | 0      | 0      | Fclk/2 <sup>8</sup>                              |
| 1      | 0      | 0      | 1      | Fclk/2 <sup>9</sup>                              |
| 1      | 0      | 1      | 0      | F <sub>CLK</sub> /2 <sup>10</sup>                |
| 1      | 0      | 1      | 1      | Fclk/2 <sup>11</sup>                             |
|        | Oth    | ers    |        | Settings are disabled                            |

Note: When you change the clock selected as  $F_{CLK}$  (change the value of the system clock control register (CKC))during the operation of the general-purpose serial communication unit (SCI), you must stop the operation of the SCI (serial channel stop register m). (STm)=000FH) after making changes.

Notice: Bits 15~8 must be set to "0".

### Remark:

- 1. F<sub>CLK</sub>: CPU/peripheral hardware clock frequency;
- 2. m: Unit number (m=0, 1);
- 3. k=0, 1.

## 12.3.3 Serial mode register mn (SMRmn)

The SMRmn register is a register that sets the operating mode of channel n, selects the operating clock  $(F_{MCK})$ , specifies whether the serial clock  $(F_{SCLK})$  input can be used, sets the start of triggering, and operates the mode settings (SSPI, UART) and selection of interrupt sources. In addition, the inverting level of the received data is set only in UART mode.

It is forbidden to overwrite the SMRmn register during operation (SEmn=1), but it is possible to overwrite the MDmn0 bit during operation.

The SMRmn register is set by a 16-bit memory manipulation instruction.

After generating a reset signal, the value of the SMRmn register changes to "0020H".

Table 12-8: Format of serial mode register mn (SMRmn) (1/2)

After reset: 0020H R/W

q: UART number (q=0, 1);

## 12.3.4 Serial communication run setting register mn (SCRmn)

The SCRmn register is the communication operation setting register of channel n, which sets the data transmission and reception modes, data and clock phases, whether to mask the error signal, parity test bits, start bits, stop bits, and data length.

It is forbidden to overwrite the SCRmn register during operation (SEmn=1).

The SCRmn register is set by means of a 16-bit memory manipulation instruction.

After generating a reset signal, the value of the SCRmn register changes to "0087H".

Table 12-9: Format of serial communication run setting register mn (SCRmn) (1/3)

| After      | reset: 0 | 087H |     |     |    |     |     | R/W |     |   |     |     |     |     |     |     |

## 12.3.5 Serial data register mn (SDRmn)

The SDRmn register is the data register (16-bit) that channel n sends and receives.

When the operation stops (SEmn=0), bit15~9 is used as a crossover setting register for the operating clock (FMCK). During operation (SEmn=1) bit15~9 is used as a transmit and receive buffer register.

If the CCSmn bit of the serial mode register mn (SMRmn) is "0", the bit15 to 9 of the SDRmn register is used. The divider clock of the operating clock (higher 7 bits) is used as the transmission clock.

The SIRmn register is set by means of a 16-bit memory manipulation instruction.

After generating a reset signal, the value of the SDRmn register changes to "0000H".

Table 12-10: Format of serial data register mn (SDRmn)

|       | After i | reset: 00 | )00H |    |    |    | R/W |   |   |   |   |   |   |   |   |   |
|-------|---------|-----------|------|----|----|----|-----|---|---|---|---|---|---|---|---|---|
|       |         |           |      |    |    |    |     |   |   |   |   |   |   |   |   |   |

| 1 | 1 | 1  | 1      | 1    | 1 | 1 | Fmck/128  |

#### Notice:

- 1. When operation is stopped (SEmn=0), bit8~0 must be cleared to zero.
- 2. When using UART, it is prohibited to set SDRmn[15:9] to "000000000B" and "000000001B".
- 3. When operation is stopped (SEmn=0), it is prohibited to rewrite SDRmn[7:0] by an 8-bit memory manipulation instruction (otherwise, all of SDRmn[15:9] is cleared to "0").

#### Remark:

- 1. For the function of the SDRmn register during operation, please refer to "12.2 Structure of general-purpose serial communication unit".
- 2. m: unit number (m=0, 1);n: channel number (n=0, 1).

## 12.3.6 Serial flag clear trigger register mn(SIRmn)

This is a trigger register used to clear each error flag for channel n.

If each bit (FECTmn, PECTmn, OVCTmn) is set to "1", the corresponding bits (FEFmn, PEFmn, OVFmn) of the serial status register mn (SSRmn) are cleared to "0". Since SDIRmn register is a trigger register, if the corresponding bit of SSRmn register is cleared, SDIRmn register will also be cleared immediately.

The SIRmn register is set by a 16-bit memory manipulation instruction.

It is possible to set the lower 8 bits of the SIRmn register with SIRmnL and by an 8-bit memory manipulation instruction.

After a reset signal is generated, the value of SIRmn register changes to "0000H".

Table 12-11: Format of serial flag clear trigger register mn (SIRmn)

|        | After reset |    |    |    |    |    |   | 0000H R/W |   |   |   |   |   |        |        |        |

|---|--------|---|--|--|--|--|--|--|--|
|   | 0      | No clearance.                                     |  |  |  |  |  |  |  |
| ĺ | 1      | Clear the OVFmn bit of the SSRmn register to "0". |  |  |  |  |  |  |  |

Note 1: Limited to SIR01, SIR11 registers.

Notice: Bits 15~3 (SIR00, SIR10 registers are bit15~2) must be set to "0".

#### Remark:

- m: unit number (m=0, 1);
   n: channel number (n=0, 1);
- 2. The read value of SIRmn register is always "0000H".

www.mcu.com.cn 298 / 624 Rev.1.0.3

## 12.3.7 Serial status register mn (SSRmn)

The SSRmn register indicates the communication status of channel n and the condition in which an error occurred. Errors represented are frame errors, parity errors, and overflow errors. Read the SSRmn registers via a 16-bit memory manipulation instruction.

It can read the lower 8 bits of the SSRmn register with SSRmnL and read the SSRmn register through the 8-bit memory manipulation instruction.

After generating a reset signal, the value of the SSRmn register changes to "0000H".

Table 12-12: Format of serial status register mn (SSRmn) (1/2)

|        | Af | ter res | et |    |    |    |   | 000 | )0H |       |       |   |   | R     |       |       |

## 12.3.8 Serial channel start register m(SSm)

The SSm register is a trigger register to set the enable communication/start count for each channel.

If a "1" is written to each bit (SSmn), the corresponding bit (SEmn) in the serial channel enable status register m (SEm) is set to a "1" (operation enable status). Since the SSmn bit is a trigger bit, the SSmn bit is cleared immediately if the SEmn bit is a "1".

The SSm register is set by a 16-bit memory manipulation instruction.

It is possible to use SSmL and set the lower 8 bits of SSm register by an 8-bit memory manipulation instruction.

After a reset signal is generated, the value of SSm register changes to "0000H".

Table 12-13: Format of serial channel start register m (SSm)

|        | /  | After res | set |    |    |    |   | 0000H |   |   |   | R/W |   |   |      |      |  |
|--------|----|-----------|-----|----|----|----|---|-------|---|---|---|-----|---|---|------|------|--|
| Symbol | 15 | 14        | 13  | 12 | 11 | 10 | 9 | 8     | 7 | 6 | 5 | 4   | 3 | 2 | 1    | 0    |  |
| SSm    | 0  | 0         | 0   | 0  | 0  | 0  | 0 | 0     | 0 | 0 | 0 | 0   | 0 | 0 | SSm1 | SSm0 |  |

| SSmn | Trigger at the beginning of channel n operation                     |
|------|---|
| 0    | No triggering.  |
| 1    | Set the SEmn bit "1" and shift to communication standby state Note. |

Note: If the SSmn bit is set to "1" during communication, communication will be stopped and enter standby state. At this time, the values of control register and shift register, SCLKmn pin and SDOmn pin, FEFmn flag, PEFmn flag and OVFmn flag remain in state.

Notice: Bits 15~2 of SSm register must be set to "0".

#### Remark:

- m: unit number (m=0, 1);
   n: channel number (n=0, 1);
- 2. The read value of SSm register is always "0000H".

www.mcu.com.cn 301 / 624 Rev.1.0.3

## 12.3.9 Serial channel stop register m(STm)

The STm register is a trigger register for setting to enable communication/stop count for each channel.

If a "1" is written to each bit (STmn), the corresponding bit (SEmn) in the serial channel enable status register m (SEm) is cleared to "0" (stop status). Since the STmn bit is a trigger bit, if the SEmn bit is "0", the STmn bit is cleared immediately.

The STm register is set by a 16-bit memory manipulation instruction.

The lower 8 bits of the STm register can be set using STmL and by an 8-bit memory manipulation instruction. After the reset signal is generated, the value of STm register changes to "0000H".

Table 12-14: Format of serial channel stop register m (STm)

|        |    | After res | set |    |    |    |   | 0000H |   |   |   | R/W |   |   |      |      |  |  |
|--------|----|-----------|-----|----|----|----|---|-------|---|---|---|-----|---|---|------|------|--|--|
| Symbol | 15 | 14        | 13  | 12 | 11 | 10 | 9 | 8     | 7 | 6 | 5 | 4   | 3 | 2 | 1    | 0    |  |  |
| STmn   | 0  | 0         | 0   | 0  | 0  | 0  | 0 | 0     | 0 | 0 | 0 | 0   | 0 | 0 | ST01 | ST00 |  |  |

| STmn | Stop trigger for channel n operation  |
|------|---|
| 0    | No triggering.  |
| 1    | Clear the SEmn bit to "0" to stop the communication operation <sup>Note</sup> . |

Note: The control register and shift register values, the SCLKmn pin and SDOmn pin, and the FEFmn flag, PEFmn flag, and OVFmn flag hold status.

Notice: Bits 15~2 of STm register must be set to "0".

#### Remark:

- m: unit number (m=0, 1);
   n: channel number (n=0, 1);
- The read value of STm register is always "0000H".

www.mcu.com.cn 302 / 624 Rev.1.0.3

## 12.3.10 Serial channel enable status register m (SEm)

The SEm register is used to confirm the allow or stop status of serial transmit and receive for each channel.

If "1" is written to each of the serial start allow register m (SSm), the corresponding bit is set to "1". If you write "1" to each bit of the serial channel stop register m (STm), the corresponding bit is cleared to "0".

For channel n, which is allowed to run, the value of the CKOmn bit (serial clock output of channel n) of the serial output register m (SOm), described later, cannot be rewritten by software, and the value reflected by the communication run is output from the serial clock pin.

The value of the CKOmn bit in the SOm register can be set by software for channel n that is stopped, and the value is output from the serial clock pin. Thus, arbitrary waveforms such as start conditions or stop conditions can be generated by software.

The SEm register is read by a 16-bit memory manipulation instruction.

The lower 8 bits of the SEm register can be read with SEmL and by 8-bit memory manipulation instructions.

After the reset signal is generated, the value of SEm register becomes "0000H".

Table 12-15: Format of serial channel enable status register m (SEm)

|        |    | After re | set |    |    |    |   | 0000H |   |   |   | R |   |   |      |      |  |

| SEmn   | 0  | 0        | 0   | 0  | 0  | 0  | 0 | 0     | 0 | 0 | 0 | 0 | 0 | 0 | SE01 | SE00 |  |

| SEmn | Indication of the enable or stop state of channel n operation |
|------|---|
| 0    | Run stop state  |
| 1    | Run enable state  |

Remark: m: unit number (m=0, 1);

n: channel number (n=0, 1).

www.mcu.com.cn 303 / 624 Rev.1.0.3

## 12.3.11 Serial output enable register m (SOEm)

The SOEm register setting enable or stops the output of serial communication for each channel.

For channel n that enable serial output, the value of the SOmn bit of the serial output register m (SOm) described below cannot be rewritten by software, but the value reflected by the communication operation is output from the serial data output pin.

For channel n that stops the serial output, the value of the SOMn bit of the SOm register can be set by software and output from the serial data output pin. Thus, arbitrary waveforms such as start conditions or stop conditions can be generated by software.

The SOEm register is set by the 16-bit memory manipulation instruction.

I can set the low 8 bits of the SOEm register with SOEmL and through the 8-bit memory manipulation instruction.

After generating a reset signal, the value of the SOEm register changes to "0000H".

Table 12-16: Format of serial output enable register m (SOEm)

|        | P  | After res | set |    |    |    |   | 0000H | • |   | J | R/W |   |   |       |       |  |  |

| SOEmn | Channel n serial output enable or stop     |
|-------|--|
| 0     | Stop the output of serial communication.   |
| 1     | Enable the output of serial communication. |

Remark: Bits 15~2 of SOEm register are set to "0".

m: unit number (m=0, 1);

n: channel number (n=0, 1).

www.mcu.com.cn 304 / 624 Rev.1.0.3

## 12.3.12 Serial output register m (SOm)

The SOm register is a buffer register for the serial output of each channel.

The value of the SOmn bit of this register is output from the serial data output pin of channel n.

The value of the CKOmn bit of this register is output from the serial clock output pin of channel n.

The SOmn bit of this register can be rewritten by software only when serial output is disabled (SOEmn=0). When serial output is allowed (SOEmn=1), the value of the SOmn bit of this register can only be changed by serial communication, ignoring software rewriting.

The CKOmn bit of this register can be rewritten by software only when the channel is stopped (SEmn=0). When the channel is allowed to run (SEmn=1), software rewriting is ignored and the value of the CKOmn bit in this register can only be changed via serial communication.

To use the pins of the serial interface for non-serial interface functions such as port functions, the corresponding CKOmn bit and SOmn bit must be set to "1".

The SOm register is set by a 16-bit memory manipulation instruction.

After the reset signal is generated, the value of SOm register changes to "0303H".

Table 12-17: Format of serial output register m (SOm)

|        | Α  | fter res | et |    |    |    |       |       | R/W |   |   |   |   |   |      |      |
|--------|----|----------|----|----|----|----|-------|-------|-----|---|---|---|---|---|------|------|
| Symbol | 15 | 14       | 13 | 12 | 11 | 10 | 9     | 8     | 7   | 6 | 5 | 4 | 3 | 2 | 1    | 0    |
| SOm    | 0  | 0        | 0  | 0  | 0  | 0  | CKOm1 | CKOm0 | 0   | 0 | 0 | 0 | 0 | 0 | SOm1 | SOm0 |

|   | CKOmn | Serial clock output for channel n            |
|---|-------|--|
| ſ | 0     | The output value of the serial clock is "0". |
| Ī | 1     | The output value of the serial clock is "1". |

| SOmn | Serial data output for channel n            |
|------|---|
| 0    | The output value of the serial data is "0". |
| 1    | The output value of the serial data is "1". |

Notice: Bits 15~10 and bits 7~2 of SOm register must be set to "0".

Remark: m: unit number (m=0, 1);

n: channel number (n=0, 1).

## 12.3.13 Serial output level register m (SOLm)

The SOLm register is a register for setting the data output level inversion for each channel.

This register can be set only in UART mode. In SSPI mode, the corresponding bits must be set to "0". Only when serial output is allowed (SOEmn=1), set the inverse of each channel n of this register to reflect to the pin output. When serial output is disabled (SOEmn=0), the value of the SOmn bit is output directly. It is prohibited to rewrite the SOLm register during operation (SEmn=1).

The SOLm register is set by a 16-bit memory manipulation instruction.

It is possible to set the lower 8 bits of SDOLm register with SOLmL and by 8-bit memory manipulation instruction.

After the reset signal is generated, the value of SOLm register changes to "0000H".

Table 12-18: Format of the serial output level register m (SOLm)

|        |    | After res | set |    |    | 0000H |   |   |   |   |   |   | R/W |   |   |       |  |  |
|--------|----|-----------|-----|----|----|-------|---|---|---|---|---|---|-----|---|---|-------|--|--|
| Symbol | 15 | 14        | 13  | 12 | 11 | 10    | 9 | 8 | 7 | 6 | 5 | 4 | 3   | 2 | 1 | 0     |  |  |
| SOLm   | 0  | 0         | 0   | 0  | 0  | 0     | 0 | 0 | 0 | 0 | 0 | 0 | 0   | 0 | 0 | SOLm0 |  |  |

| SOLmn | Selection of channel n transmit data level inversion in UART mode |
|-------|---|
| 0     | Output the communication data directly.                           |
| 1     | Invert the communication data to output.                          |

Notice: Bits 15~1 of SOL0, SOL1 and SOL2 registers must be set to "0".

Remark: m: unit number (m=0, 1);

n: channel number (n=0).

When UART transmission is performed, an example of level inversion of the transmitted data is shown in Figure 12-2.

Figure 12-2: Example of level inversion for transmitting data

Remark: m: unit number (m=0, 1); n: channel number (n=0).

## 12.3.14 Input switching control register (ISC)

When LIN-bus communication is implemented via UART0, the ISC1 bits and ISC0 bits of the ISC registers are used for coordination of external interrupts and timer array units. If bit0 is placed at "1", the input signal of the serial data input (RxD0) pin is selected as the input to the external interrupt (INTP0), so it can pass THE INTP0 interrupt detects the wake-up signal.

If bit1 is set to "1", the input signal of the serial data input (RxD0) pin is selected as the input to the timer, so the wake signal can be detected by the timer and the low width of the break field and the pulse width of the synchronization field can be measured.

The SSIE00 bit controls the SS00 pin input of channel 0 in the slave mode of SSPI00 communication. During the period when a high level is input to the SS00 pin, transmission and reception are not performed even if a serial clock is input; during the period when a low level is input to the SS00 pin, transmission and reception are performed according to the setting of each mode if a serial clock is input.

The ISC register is set by an 8-bit memory manipulation instruction.

After a reset signal is generated, the value of the ISC register becomes "00H".

Table 12-19: Table of input switching control register (ISC)

| Address: | 40040473H | After re | eset: 00H | R/W |   |   |      |      |  |  |
|----------|-----------|----------|-----------|-----|---|---|------|------|--|--|
| Symbol   | 7         | 6        | 6 5       |     | 3 | 2 | 1    | 0    |  |  |
| ISC      | SSIE00    | 0        | 0         | 0   | 0 | 0 | ISC1 | ISC0 |  |  |

| SSIE00 | Setting of SS00 input for channel 0 in slave mode of SSPI00 communication |
|--------|---|
| 0      | SS00 pin input is invalid.  |
| 1      | SS00 pin input is valid.  |

| ISC1 | Input switching of channel 3 of Timer4  |
|------|---|
| 0    | Use the input signal from the TI03 pin as an input to the timer (normally operating).   |
|      | Use the input signal on the RxD0 pin as a timer input (detects the wake-up signal and measures the low-level width of the break field and the pulse width of the sync field). |

| ISC0 | Input switching of external interrupt (INTP0)   |
|------|---|
| 0    | Use the input signal on the INTP0 pin as an external interrupt input (normally operating).        |
| 1    | Use the input signal on the RxD0 pin as an external interrupt input (detecting a wake-up signal). |

Notice: Bits 6~2 must be set to "0".

## 12.3.15 Noise filter enable register 0 (NFEN0)

The NFEN0 register sets whether the noise filter is used for the input signal of each channel's serial data input pin.

For pins used for SSPI communication, the corresponding bit must be "0" to invalidate the noise filter. For pins used for UART communication, the corresponding bit "1" must be set to make the noise filter effective.

When the noise filter is active, the 2 clocks are detected to be consistent after synchronization through the operating clock (F<sub>MCK</sub>) of the object channel; When the noise filter is invalid, synchronization is performed only through the operating clock (F<sub>MCK</sub>) of the object channel.

The NFEN0 register is set by an 8-bit memory manipulation instruction.

After generating a reset signal, the value of the NFEN0 register changes to "00H".

Table 12-20: Format of noise filter enable register 0 (NFEN0)

| Address: | 40040470 | H After res | set: 00 | DΗ |   |         |   |         |

| When used as | a function other than the RxD0 pin, the SNFEN00 must be set to "0". |  |  |  |  |  |  |  |  |

Notice: Bits 7, 5, 3, 1 must be set to "0".

Rev.1.0.3 www.mcu.com.cn 308 / 624

# 12.3.16 Registers controlling port functions of serial input/output pins

When using a general-purpose serial communication unit, the control registers for the multiplexed port function (Port Mode Register (PMxx), Port Multiplexing Function Configuration Register (PxxCFG), Port Output Mode Register (POMxx), and Port Mode Control Register (PMCxx) must be set).

For details, please refer to "Chapter 2 Port Function".

When using the multiplexed port of the serial data output pin or the serial clock output pin as the serial data output or serial clock output, the bits of the corresponding port mode control register (PMCxx) and the bit of the port mode register (PMxx) corresponding to each port are "0". In this case, the bit of the port register (Pxx) can be "0" or "1".

In addition, when used for N-channel open-drain output mode, the bit of the port output mode register (POMxx) corresponding to each port must be "1".

When using the multiplexed port of the serial data input pin or serial clock input pin as serial data input or serial clock input, you must set the bit of the Port Mode Register (PMxx) corresponding to each port to "1" and set the bit of the Port Mode Control Register (PMCxx) to "0". In this case, the Port Register (Pxx) bits can be "0" or "1".

www.mcu.com.cn 309 / 624 Rev.1.0.3

## 12.4 Operation stop mode

Each serial interface of a general-purpose serial communication unit has an operation stop mode. Serial communication is not possible in operation stop mode, so power consumption is reduced. In addition, pins for the serial interface can be used as port functions in operation stop mode.

## 12.4.1 Stopping the operation by units

The unit stop is set by peripheral enable register 0/2 (PER0/2).

Per0/2 registers are registers that are set to enable or disable clocks to each peripheral hardware. Reduce power consumption and noise by stopping clocks to unused hardware.

To stop general-purpose serial communication unit 0, the bit2 (SCI0EN) of PER0 must be set to "0"; To stop general-purpose serial communication unit 1, the bit3 (SCI1EN) of PER0 must be set to "0"

Peripheral enable register 0 (PER0) ...... Set "0" to the bit corresponding to the bit where SCIm is to be stopped.

Table 12-21: Setting of peripheral enable register 0 (PER0) when stopping operation by unit

| Symbol | 7     | 6 | 5     | 4      | 3      | 2      | 1      | 0      |
|--------|-------|---|-------|--------|--------|--------|--------|--------|
| PER0   | RTCEN | 0 | ADCEN | IICAEN | SCI1EN | SCI0EN | TM41EN | TM40EN |

| SCImEN | Provides control of the input clock of the general-purpose serial communication unit m.   |
|--------|---|
| 0      | <ul> <li>Stop to supply the input clock.</li> <li>The SFR used by the general-purpose serial communication unit m cannot be written.</li> <li>The general-purpose serial communication unit m is in the reset state.</li> </ul> |
| 1      | <ul><li>Enables an input clock to be supplied.</li><li>Can read and write SFRs used by the general-purpose serial communication unit m.</li></ul>   |

#### Remark:

- 1. When the SCImEN bit is "0", the write operation of the control register of the general-purpose serial communication unit m is ignored, and the read values are initial values. However, the following registers are excluded:
  - ① Input switching control register (ISC)
  - 2 Noise filter enable register (NFEN0)
  - ③ Port multiplexing function configuration register (PxxCFG)
  - Port output mode register (POMx)
  - ⑤ Port output mode register (PMx)
  - 6 Port mode register (Px)
- 2. **x**: Bits are not used by the general-purpose serial communication units (depending on the setting of other peripheral functions).

0/1: Set "0" or "1" depending on the user's purpose.

## 12.4.2 Stopping the operation by channels

The stopping of the operation by channels is set using each of the following registers.

(1) Serial channel stop register m (STm) ... This register is a trigger register that is used to enable communication/stop count by each channel.

| Symbol | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1    | 0    |
|--------|----|----|----|----|----|----|---|---|---|---|---|---|---|---|------|------|
| STm    | 0  | 0  | 0  | 0  | 0  | 0  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | STm1 | STm0 |

- ① Clears the SEmn bit to 0 and stops the communication operation
- ② Because the STmn bit is a trigger bit, it is cleared immediately when SEmn = 0.

(2) Serial channel enable status register m (SEm) ... This register indicates whether data transmission/reception operation of each channel is enabled or stopped.

| Symbol | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1    | 0    |
|--------|----|----|----|----|----|----|---|---|---|---|---|---|---|---|------|------|
| SEm    | 0  | 0  | 0  | 0  | 0  | 0  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | SEm1 | SEm0 |

- ① 0: Operation stop state
- The SEm register is a read-only status register, whose operation is stopped by using the STm register. With a channel whose operation is stopped, the value of the CKOmn bit of the SOm register can be set by software.
- (3) Serial output enable register m (SOEm) ... This register is a register that is used to enable or stop output of the serial communication operation of each channel.

| Sym | loc | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1     | 0     |
|-----|-----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|-------|-------|
| SOE | m   | 0  | 0  | 0  | 0  | 0  | 0  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | SOE01 | SOE00 |

- ① 0: Stops output by serial communication operation
- ② The value of the SOmn bit of the SOm register can be set by software for channels where serial output has been stopped.
- (4) Serial output register m (SOm) ... This register is a buffer register for serial output of each channel.

| Symbol | 15 | 14 | 13 | 12 | 11 | 10 | 9     | 8     | 7 | 6 | 5 | 4 | 3 | 2 | 1    | 0    |
|--------|----|----|----|----|----|----|-------|-------|---|---|---|---|---|---|------|------|
| SOm    | 0  | 0  | 0  | 0  | 0  | 0  | CKOm1 | CKOm0 | 0 | 0 | 0 | 0 | 0 | 0 | SOm1 | SOm0 |

- ① CKOm1/0: 1: output value of the serial clock is "1"; 0: output value of the serial clock is "0"
- 2 SOm1/0: 1: output value of the serial clock is "1"; 0: output value of the serial clock is "0"
- When using the pin corresponding to each channel as a port function, the corresponding CKOmn bit and SOmn bit must be "1".

Remark: Limited to general-purpose serial communication unit 0.

m: unit number (m=0, 1);

n: channel number (n=0, 1);

0/1: Set "0" or "1" according to the user's purpose.

## 12.5 3-wire serial I/O (SSPI00, SSPI01, SSPI10, SSPI11) communication

This is a clock synchronization communication function implemented by three lines of serial clock (SCLK) and serial data (SDI and SDO).

[Data transmission and reception]

- (1) Data length of 7~16 bits
- (2) Phase control of transmit/receive data
- (3) MSB/LSB preferred option

#### [Clock control]

- (1) Master/slave selection
- (2) Phase control of I/O clock
- (3) Setting of transfer period by prescaler and internal counter
- (4) Maximum transfer rate

During master communication: Max.F<sub>CLK</sub>/2 During slave communication: Max.F<sub>MCK</sub>/6

#### [Interrupt function]

Transfer end interrupt, buffer empty interrupt

#### [Error detection flag]

Overflow error

Channels 0~1 of SCI0 and channels 0~1 of SCI1 are channels that support 3-wire serial I/O (SSPI00, SSPI01, SSPI10, SSPI11).

The 3-wire serial I/O (SSPI00, SSPI01, SSPI10, SSPI11) has the following six communication operations.

- (1) Master transmission (refer to 12.5.1)
- (2) Master reception (refer to 12.5.2)
- (3) Master transmission and reception (refer to 12.5.3)
- (4) Slave transmission (refer to 12.5.4)
- (5) Slave reception (refer to 12.5.5)
- (6) Slave transmission and reception (refer to 12.5.6)

Notice: It must be used within the range that satisfies the SCLK cycle time ( $T_{KCY}$ ) characteristics. Refer to the datasheet for details.

### 12.5.1 Master transmission

Master transmission refers to the operation of this product output transmission clock and sending data to other devices.

Table 12-22: Master transmission
Plo0 SSPI01 SS

| 3-wire serial I/O               | SSPI00  | SSPI01                                  | SSPI10             | SSPI11             |  |  |  |  |  |

Figure 12-6: Restart steps of master transmission

Notice: If you override PER0 in the abort settings to stop providing the clock, you must make the initial settings instead of restarting them when the communication object (slave) stops or when the communication ends.

#### (3) Process flow (single transmit mode)

Figure 12-7: Timing diagram of master transmission (single send mode) (type 1: DAPmn= 0, CKPmn = 0)

Remark: m: unit number (m=0, 1);

n: channel number (n=0, 1);

p: SSPI number (p=00, 01, 10, 11).

www.mcu.com.cn 317 / 624 Rev.1.0.3

Figure 12-8: Flowchart of master transmission (single transmit mode) SSPI communication starts relevant initial configuration, refer to the previous diagram (select SCI initial configuration transmission completion interrupt) configure transmission data and data count, clear communication completion flag (via software, any configured internal RAM reserved region, transmit data pointer, transmit data communication data count and communication completion flag). main program set to enable interrupt after clear interrupt request flag(IFxx) and release enable interrupt interrupt mask (MKxx). from reserved region read and transmit data and write transmit data into SDRmn write to SDRmn, update transmit data pointer output SDOp and SCLKp signal (start communication) via writing into SDRmn wait transmission completes. if transmission completion interrupt occurs, jump to interrupt process program. transmission completion interrupt No transmit next data? interrupt process program if there are data to be transmitted, then read write transmit data into SDRmn set communication completion flag transmit data from reserved region and write into SDRmn, update transmit data pointer. Else, set communication completion flag to 1. **RETURN** No transmission completes? check whether transmission completed via confirming communication completion flag. disable interrupt (mask). main program set STmn bit to 1. communication completed.

#### (4) Process flow (continuous transmit mode)

Figure 12-9: Timing diagram of the master transmission (continuous transmit mode) (type 1: DAPmn= 0, CKPmn = 0)

Note: If the transmit data is written to the SDRmn register during the time when the BFFmn bit of the serial status register mn (SSRmn) is "1" (when valid data is stored in the serial data register mn (SDRmn)), the transmit data is rewritten;

Notice: The MDmn0 bit of the serial mode register mn (SMRmn) can be rewritten even in operation.

However, in order to catch the end-of-transmission interruption of the last sent data, it must be rewritten before the last bit of transmission begins.

Remark: m: unit number (m=0, 1);

n: channel number (n=0, 1);

p: SSPI number (p=00, 01, 10, 11).

www.mcu.com.cn 319 / 624 Rev.1.0.3

Remark: ① to ⑥ correspond to ① to ⑥ in "Figure 12-9 Timing Diagram of Master Transmission (Continuous Transmission Mode)".

## 12.5.2 Master reception

Master reception refers to the operation of this product output transmission clock and receiving data from other devices.

Table 12-23: Master reception

| 3-wire serial I/O    | SSPI00  | SSPI01             | SSPI10             | SSPI11             |  |  |  |

Figure 12-21: Stop steps for master transmission and reception

(3) Process flow (single transmit and receive mode)

Figure 12-23: Timing diagram of master transmit and receive (single transmit and receive mode) (type 1: DAPmn=0, CKPmn=0)

Remark: m: unit number (m=0, 1);

n: channel number (n=0, 1);

p: SSPI number (p=00, 01, 10, 11).

www.mcu.com.cn 334 / 624 Rev.1.0.3

Figure 12-24: Flowchart of master transmit and receive (single transmit and receive mode) SSPI communication starts

(4) Process flow (continuous transmit and receive mode)

Figure 12-25: Timing diagram of master transmit and receive (continuous transmit and receive mode) (type 1: DAPmn=0, CKPmn=0)

Note 1: If the transmit data is written to the SDRmn register during the time when the BFFmn bit of the serial status register mn (SSRmn) is "1" (when valid data is stored in the serial data register mn (SDRmn)), the transmit data is rewritten.

Note 2: If the SDRmn register is read during this time, the transmit data can be read. At this time, the transmission operation is not affected.

Notice: It is possible to rewrite the MDmn0 bit of the Serial Mode Register mn (SMRmn) even during operation. However, in order to catch the end-of-transmission interrupt for the last data sent, the rewrite must be done before the transmission of the last bit begins.

# 12.5.6 Slave transmission and reception

Slave transmission and reception refers to the operation of data transmission and reception by microcontrollers and other devices of this product in the state of transmitting clocks from other device inputs.

Table 12-27: Slave transmission and reception

|   | Z7. Clave transmission  |   |  |  |
|---|---|---|--|--|

Only set bit of target channel to 1. 15 11 10 0 SSm SSm3 SSm2 SSm1 SSm0 0 0 0 0 0/1

Notice: The transmit data must be set to the SDRmn register before the master device starts outputting the clock.

Remark: m: unit number (m=0, 1);

n: channel number (n=0, 1);

p: SSPI number (p=00, 01, 10, 11);

□ : Fixed set in SSPI master receive mode; ■ : Cannot be set (initial value is set);

x: This is a bit that cannot be used in this mode (sets the initial value if it is not used in other modes either);

0/1: Set "0" or "1" according to the user's purpose.

#### (2) Procedure

Figure 12-42: Initial setup steps for slave transmission and reception

Notice: The transmit data must be set to the SDRmn register before the master device starts outputting the clock.

Figure 12-43: Stop steps for slave transmission and reception stop configuration starts if there are ongoing data transmission, No (selection) TSFmn = 0? then wait till transmission completed. (if need urgent stop, then no need to wait). set STmm bit of target channel to 1. (mandatory) write into STm register (SEmn=0: set to operation stop state). modify SOEm register set SOEmn bit to 0, stop output of target (mandatory) configuration channel modify SOm register when emergency stop, based on needs, (selection) configuration modify serial data (SOmn) level of the target channel. stop clock of universal serial communication configure PER0 register (selection) unit, set to reset state finish termination configuration, enter into configuration ends. next processing.

Figure 12-44: Restart steps for slave transmission and reception

## Notice:

- 1. The transmit data must be set to the SDRmn register before the master device starts outputting the clock.
- 2. If PER0 is rewritten in the abort setting to stop providing the clock, the initial setting must be made after the communication object (master device) stops or communication ends instead of the restart setting.

(3) Process flow (single transmit and receive mode)

Figure 12-45: Timing diagram of slave transmit and receive (single transmit and receive mode) (type 1: DAPmn=0, CKPmn=0)

Remark: m: unit number (m=0, 1);

n: channel number (n=0, 1);

p: SSPI number (p=00, 01, 10, 11).

www.mcu.com.cn 357 / 624 Rev.1.0.3

SSPI communication starts Refer to the previous setting diagram (select transmit SCI initial configuration end interrupt) For transmitting and receiving data, set the save area and the number of data (the save area in the internal RAM, the transmit configure transmit and receive data pointer, the receive data pointer, and the number of communication data can be set arbitrarily by software). data main Set to allow interrupts after clearing the interrupt enable interrupt request flag (IFxx) and unmasking the interrupt (MKxx). Read the transmit data from the buffer and write it to Write send data to SDRmn SDRmn, updating the transmit data pointer. Communication is started by the clock provided by the master device. Waiting for the end of sending and receiving If an interrupt is generated by sending an end, it is transferred to the interrupt handler. End of transmission interruption interrupt process Read and receive SDRmn Read the received data and write it to the save area, update the received data pointer. data **RETURN** No End of sending and receiving? Yes Yes Send and receive the next data? Updates the number of communication data and confirms that there is no next send and receive data. main No disable interrupt (mask). set STmn bit to 1.

Figure 12-46: Flowchart of slave slave transmit and receive (single transmit and receive mode)

Notice: The SIOp register must be set for transmit data before the master device begins to output the clock.

communication completed.

(4) Process flow (continuous send and receive mode)

Figure 12-47: Timing diagram of slave transmit and receive (continuous transmit and receive mode) (type 1: DAPmn=0, CKPmn=0)

Note 1: If the transmit data is written to the SDRmn register during the time when the BFFmn bit of the serial status register mn (SSRmn) is "1" (when valid data is stored in the serial data register mn (SDRmn)), the transmit data is rewritten;

Note 2: If the SDRmn register is read during this period, the data can be read and sent. At this point, the transfer run is not affected.

Notice: It is possible to rewrite the MDmn0 bit of the Serial Mode Register mn (SMRmn) even during operation. However, in order to catch the end-of-transmission interrupt for the last data sent, the rewrite must be done before the transmission of the last bit begins;

## Remark:

- 1. ① to ⑧ in the figure correspond to ① to ⑧ in "Figure 12-48 Flowchart of Slave Transmit and Receive (Continuous Transmit and Receive Mode)";
- 2. m: unit number (m=0, 1);
  - n: channel number (n=0, 1);
  - p: SSPI number (p=00, 01, 10, 11).

www.mcu.com.cn 359 / 624 Rev.1.0.3

Figure 12-48: Flowchart of slave transmit and receive (continuous transmit and receive mode)

Notice: The transmit data must be set to the SDRmn register before the master device starts outputting the clock.

Remark: ① to ⑧ in the figure correspond to ① to ⑧ in "Figure 12-47 Timing Diagram of Slave Transmit and Receive (Continuous Transmit and Receive Mode)".

## 12.5.7 Calculation of transmission clock frequency

3-wire serial I/O (SSPI00, SSPI01, SSPI10, SSPI11) communication transmission clock frequency can be calculated using the following calculation equations.

#### (1) Master

(Transmit clock frequency) = {Operation clock frequency of the target channel  $(F_{MCK})$ } ÷ (SDRmn [15:9] +1) ÷2[Hz]

#### (2) Slave

(Transmit clock frequency) = {Serial clock (SCLK) frequency provided by the master device} Note [Hz]

#### Remark:

- 1. The maximum allowable transmit clock frequency is F<sub>MCK</sub>/6;
- 2. It is 0~127 because the value of SDRmn [15:9] is the value of bit15~9 (0000000B~1111111B) of Serial Data Registermn (SDRmn);
- 3. The operating clock ( $F_{MCK}$ ) depends on bit15 (CKSmn) of the serial clock selection register m (SPSm) and the serial mode register mn (SMRmn).

|                   | 1          | 0          | 1          | 0          | Х          | Х          | Х          | Х          | Fclk/2 <sup>10</sup>              | 31.25KHz                             |
|                   | 1          | 0          | 1          | 1          | Χ          | Х          | Х          | Х          | F <sub>CLK</sub> /2 <sup>11</sup> | 15.63KHz                             |
|                   | 1          | 1          | 0          | 0          | Х          | Х          | Х          | Х          | F <sub>CLK</sub> /2 <sup>12</sup> | 7.81KHz                              |
|                   | 1          | 1          | 0          | 1          | Х          | Х          | Х          | Х          | F <sub>CLK</sub> /2 <sup>13</sup> | 3.91KHz                              |
|                   | 1          | 1          | 1          | 0          | Х          | Х          | Х          | Х          | F <sub>CLK</sub> /2 <sup>14</sup> | 1.95KHz                              |
|                   | 1          | 1          | 1          | 1          | Х          | Х          | Х          | Х          | F <sub>CLK</sub> /2 <sup>15</sup> | 977Hz                                |

Note: When you change the clock selected as fCLK (change the value of the system clock control register (CKC)), you must stop the operation of the general-purpose serial communication unit (SCI) (serial channel stop register m (STm)=000FH) after making changes.

X: Ignore

m: unit number (m=0, 1);

n: channel number (n=0, 1).

## 12.5.8 Procedure for handling errors during 3-wire serial I/O communication (SSPI00, SSPI01, SSPI10, SSPI11)

The procedure for handling an error during 3-wire serial I/O (SSPI00, SSPI01, SSPI10, SSPI11) communication is shown in Table 12-29.

Table 12-29: Processing steps when an overflow error occurs

|  | <u> </u>  |  |
|--|---|--|
| Software operation   | Hardware status   | Remark   |
| Read Serial Data Registermn → (SDRmn).                           | The BFFmn bit of the SSRmn register is "0" and channel n is receivable. | This is to prevent an overflow error from occurring if the next reception ends during error handling.                              |
| Read Serial Status Registermn (SSRmn).                           |   | Determines the type of error and reads the value for clearing the error flag.  |
| Write "1" to the serial flag clear trigger register mn (SDIRmn). | Clear the error flag.   | Errors during read operations can only be cleared by writing the read value of the SSRmn register directly to the SDIRmn register. |

Remark: m: unit number (m=0, 1);

n: channel number (n=0, 1).

# 12.6 Operation of clock-synchronous serial communication with slave selection input function

Channel 0 of SCI0 is a channel that supports clock-synchronous serial communication with a slave select input function.

[Data transmission and reception]

- (1) Data length of 7~16 bits
- (2) Phase control of transmit/receive data
- (3) MSB/LSB preferred option
- (4) Level setting for transmit/receive data

#### [Clock control]

- (1) Phase control of I/O clock
- (2) Setting of transfer period by prescaler and internal counter
- (3) Maximum transmission rate Note Slave communication: Max.F<sub>MCK</sub>/6

[Interrupt function]

Transfer end interrupt, buffer empty interrupt

[Error detection flag]

Overflow error

The slave selection input function has the following 3 types of communication operation:

- (1) Slave transmission (refer to 12.6.1)
- (2) Slave reception (refer to 12.6.2)
- (3) Slave transmission and reception (refer to 12.6.3)

Notice: It must be used within the range that satisfies the SCLK cycle time ( $T_{KCY}$ ) characteristics. Refer to the datasheet for details.

www.mcu.com.cn 364 / 624 Rev.1.0.3

The slave selection input function enables a master to communicate with multiple slave devices. The master outputs a slave selection signal to a slave device (1) of the communication object, and each slave device judges whether it is selected as the communication object and controls the output of the SDO pin. When selected as a slave device of the communication object, the SDO pin is able to communicate sending data to the master device; When a slave device is not selected as a communication object, the SDO pin becomes a high output, so it is necessary to set the SDO pin to Nch-O.D and pull up the node when connecting multiple slaves. In addition, transmission and reception are not performed even if the serial clock of the master device is input.

Figure 12-49: Example of slave selection input function

#### Notice:

- 1. Select the SDO00 pin to N-channel open drain output mode;
- 2. A slave selection signal must be output by the operation of the port.

Figure 12-50: Timing diagram of slave select input function

When SSmn is high, no transmission is performed even at the falling edge of SCKmn (serial clock), and no sampling of received data is performed synchronously with the rising edge.

When SSmn is low, data is output (shifted) synchronously with the falling edge of the serial clock and data is received synchronously with the rising edge.

When the DAPmn bit is "1", if the data is sent when SSmn is set to be high, the initial data (bit7) is provided to the data output. However, even the rising edge of the SCLKmn (serial clock) is not shifted, and the received data is not sampled in sync with the falling edge. If SSmn goes low, the output data is synchronized with the next rising edge (shift) and the data is received synchronously with the falling edge.

Remark: m: unit number (m=0); n: channel number (n=0).

#### 12.6.1 Slave transmission

Slave transmission refers to the operation of this product to send data to other devices in the state of transmitting clocks from other device inputs.

Table 12-30: Slave transmission

| Slave select input function | SSPI00  |  |  |  |  |  |  |  |
|-----------------------------|---|--|--|--|--|--|--|--|
| Target channel              | Channel 0 of SCI0   |  |  |  |  |  |  |  |
| Pins used                   | SCLKOI00, SDO00, SS00   |  |  |  |  |  |  |  |
|                             | INTSSPI00   |  |  |  |  |  |  |  |
| Interrupt                   | Selectable transmission end interrupt (single transmission mode) or buffer empty interrupt (continuous transmission mode).  |  |  |  |  |  |  |  |
| Error detection flag        | Only the overflow error detection flag (OVFmn).   |  |  |  |  |  |  |  |
| Transfer data length        | 7~16 bits   |  |  |  |  |  |  |  |
| Transfer rate               | Max.F <sub>MCK</sub> /6[Hz] <sup>Note1,2</sup>  |  |  |  |  |  |  |  |
| Data phase                  | It can be selected by the DAPmn bit of the SCRmn register.  DAPmn=0: Start data output when the serial clock starts running.  DAPmn=1: Start data output half a clock before the serial clock starts running. |  |  |  |  |  |  |  |
| Clock phase                 | It can be selected by the CKPmn bit of the SCRmn register. CKPmn=0: Non-reverse CKPmn=1: Reverse  |  |  |  |  |  |  |  |
| Data direction              | MSB or LSB first  |  |  |  |  |  |  |  |
| Slave select input function | The operation of the slave selection function can be selected.  |  |  |  |  |  |  |  |

Note 1: The maximum transfer rate is F<sub>MCK</sub>/6 [Hz] because the external serial clock input to the SCLK00 pin is internally sampled and then used.

Note 2: It must be used within the scope of peripheral functional characteristics that meet this condition and meet the electrical characteristics (see data sheret).

F<sub>MCK</sub>: Operation clock frequency of target channel

p: SSPI number (p=00).

## 12.6.2 Slave reception

Slave reception refers to the operation of this product receiving data from other devices in the state of transmitting clocks from other devices.

Table 12-31: Slave reception

| Slave select input function | SSPI00  |
|-----------------------------|---|
| Target channel              | Channel 0 of SCI0   |
| Pins used                   | SCLKOI00, SDI00, SS00   |
| Interrupt                   | INTSSPI00   |
| Interrupt                   | Limited to end-of-transmit interrupts (buffer empty interrupts are prohibited).   |
| Error detection flag        | Only the overflow error detection flag (OVFmn).   |
| Transfer data length        | 7~16 bits   |
| Transfer rate               | Max.F <sub>MCK</sub> /6[Hz] <sup>Note1,2</sup>  |
| Data phase                  | It can be selected by the DAPmn bit of the SCRmn register.  DAPmn=0: Start data output when the serial clock starts running.  DAPmn=1: Start data output half a clock before the serial clock starts running. |
| Clock phase                 | It can be selected by the CKPmn bit of the SCRmn register. CKPmn=0: Non-reverse CKPmn=1: Reverse  |
| Data direction              | MSB or LSB first  |
| Slave select input function | The operation of the slave selection input function can be selected.  |

Note 1: The maximum transfer rate is  $F_{MCK}/6$  [Hz] because the external serial clock input to the SCLK00 pin is internally sampled and then used.

Note 2: It must be used within the scope of peripheral functional characteristics that meet this condition and meet the electrical characteristics (see data sheret).

## 12.6.3 Slave transmission and reception

Slave transmission and reception refers to the operation of data transmission and reception of this product and other devices in the state of input transmission clock from other devices.

Table 12-32: Slave transmission and reception

| Slave select input function | SSPI00  |
|-----------------------------|---|
| Target channel              | Channel 0 of SCI0   |
| Pins used                   | SCLKOI00, SDI00, SDO00, SS00  |
|                             | INTSSPI00   |
| Interrupt                   | Selectable transmission end interrupt (single transmission mode) or buffer empty interrupt (continuous transmission mode).  |
| Error detection flag        | Only the overflow error detection flag (OVFmn).   |
| Transfer data length        | 7~16 bits   |
| Transfer rate               | Max.F <sub>MCK</sub> /6[Hz] <sup>Note 1,2</sup>   |
| Data phase                  | It can be selected by the DAPmn bit of the SCRmn register.  DAPmn=0: Start data output when the serial clock starts running.  DAPmn=1: Start data output half a clock before the serial clock starts running. |
| Clock phase                 | It can be selected by the CKPmn bit of the SCRmn register. CKPmn=0: Non-reverse CKPmn=1: Reverse  |
| Data direction              | MSB or LSB first  |
| Slave select input function | The operation of the slave selection input function can be selected.  |

Note 1: The maximum transfer rate is F<sub>MCK</sub>/6 [Hz] because the external serial clock input to the SCLK00 pin is internally sampled and then used.

Note 2: It must be used within the scope of peripheral functional characteristics that meet this condition and meet the electrical characteristics (see data sheret).

F<sub>MCK</sub>: Operation clock frequency of target channel

m: unit number (m=0);

n: channel number (n=0).

Figure 12-70: Flowchart of slave transmit and receive (single transmit and receive mode)

Notice: The SDRmn register must be set for transmit data before the master device begins to output the clock.

m: unit number (m=0);

n: channel number (n=0);

p: SSPI number (p=00).

(4) Process flow (continuous transmit and receive mode)

Figure 12-71: Timing diagram of slave transmit and receive (continuous transmit and receive mode) (type 1: DAPmn=0, CKPmn=0)

Note 1: If the transmit data is written to the SDRmn register during the time when the BFFmn bit of the serial status register mn (SSRmn) is "1" (when valid data is stored in the serial data register mn (SDRmn)), the transmit data is rewritten.

Note 2: If the SDRmn register is read during this time, the transmit data can be read. At this time, the transmission operation is not affected.

Notice: The MDmn0 bit of the serial mode register mn (SMRmn) can be rewritten even in operation. However, in order to catch the end-of-transmission interruption of the last sent data, it must be rewritten before the last bit of transmission begins.

## 12.6.4 Calculation of transmission clock frequency

The transmit clock frequency of the slave select input function (SSPI00) communication can be calculated using the following calculation equation.

#### (1) Slave

(Transmit clock frequency) = {Serial clock (SCLK) frequency provided by the master device} Note 1[Hz]

Note 1: The maximum allowable transmit clock frequency is  $F_{MCK}/6$ .

m: unit number (m=0) n: channel number (n=0) p: SSPI number (p=00).

Table 12-13: Selection of slave select input function operation clock

Note: To change the clock selected as  $F_{CLK}$  (change the value of the system clock control register (CKC)), the change must be made after stopping the operation of the general-purpose serial communication unit (SCI) (serial channel stop register m (STm) = 000FH).

X: Ignore

m: unit number (m=0) n: channel number (n=0).

## 12.6.5 Procedure for handling errors during clock-synchronous serial communication with the slave selection input function

The processing steps for errors that occur during clock synchronization serial communication with the slave select input function are shown in Table 12-34.

Table 12-34: Processing steps when an overflow error occurs

| Software operation   | Hardware status   | Remark   |  |  |  |
|--|---|--|--|--|--|
| Read Serial Data Registermn — (SDRmn).                           | The BFFmn bit of the SSRmn register is "0" and channel n is receivable. | This is to prevent an overflow error from occurring if the next reception ends during error handling.                              |  |  |  |
| Read serial status register mn (SSRmn).                          | -   | Determines the type of error and reads the value for clearing the error flag.  |  |  |  |
| Write "1" to the serial flag clear trigger register mn (SDIRmn). | Clear the error flag.   | Errors during read operations can only be cleared by writing the read value of the SSRmn register directly to the SDIRmn register. |  |  |  |

Remark: m: unit number (m=0) n: channel number (n=0).

Rev.1.0.3 395 / 624 www.mcu.com.cn

## 12.7 Operation of UART (UART0~UART1) communication

This is an asynchronous function using two lines: serial data transmission (TxD) and serial data reception (RxD) lines. By using these two communication lines, data is sent and received asynchronously (using the internal baud rate) with other communicating parties by data frame (consisting of start bits, data, parity bits, and stop bits). Full-duplex asynchronous UART communication can be achieved by using two channels dedicated for transmit (even channel 00/10) and receive dedicated (odd channel 01/11).

[Data transmission and reception]

- (1) Data length of 7, 8, 9 or 16 bits Note
- (2) MSB/LSB preferred option
- (3) Level setting for transmit/receive data (Selects whether the level is reversed or not)
- (4) Parity bit appending and parity check functions
- (5) Stop bit appending, stop bit detection function

#### [Interrupt function]

- (1) Transfer end interrupt, buffer empty interrupt
- (2) Error interrupts caused by frame errors, parity errors, and overflow errors

#### [Error detection flag]

Framing error, parity error, or overflow error

UART0 uses channel 0 and channel 1 of SCI0.

UART1 uses channel 0 and channel 1 of SCI1.

Each channel arbitrarily selects one function to use, except for the selected function, other functions can not be run.

For example, when using UART0 for channel 0 and channel 1 of unit m, SSPI00 cannot be used.

UART has the following 2 kinds of communication operation:

- (1) UART transmission (refer to 12.7.1)
- (2) UART reception (refer to 12.7.2)

Notice: When used as aUART, the transmitter (even numbered channel) and receiver (odd numbered channel) can only be used for UART.

### 12.7.1 UART transmission

UART transmission is the operation of this product microcontroller to asynchronously send data to other devices.

An even number of the 2 channels used by UART is used for UART transmission.

Table 12-35: UART transmission

| UART                 | UARTO UART1  |  |  |  |  |  |  |  |  |
|----------------------|--|--|--|--|--|--|--|--|--|
| Target channel       | Channel 0 of SCI0  | Channel 0 of SCI1  |  |  |  |  |  |  |  |
| Pins used            | TxD0   | TxD1   |  |  |  |  |  |  |  |
|                      | INTST0   | INTST1   |  |  |  |  |  |  |  |
| Interrupt            | Selectable transmission end interrupt (single transmission mode).        | Selectable transmission end interrupt (single transmission mode) or buffer empty interrupt (continuous transmission mode). |  |  |  |  |  |  |  |
| Error detection flag | None   |  |  |  |  |  |  |  |  |
| Transfer data length | Data length of 7 bits, 8 bits, 9 bits or 16 bits                         |  |  |  |  |  |  |  |  |
| Transfer rate        | Max.Fмск/6[bps] (SDRmn[15:9]≥3), Min.FcLк/(22¹                           | Max.F <sub>мск</sub> /6[bps] (SDRmn[15:9]≥3), Min.F <sub>CLK</sub> /(22 <sup>11</sup> 128)[bps] <sup>Note</sup>            |  |  |  |  |  |  |  |
| Data phase           | Non-reverse output (default: High). Reverse output (default value: low). |  |  |  |  |  |  |  |  |
|                      | Select from the following:   |  |  |  |  |  |  |  |  |
|                      | No parity bits.  |  |  |  |  |  |  |  |  |
| Parity bit           | Appending zero parity check.   |  |  |  |  |  |  |  |  |
|                      | Appending even parity check.   |  |  |  |  |  |  |  |  |
|                      | Appending odd parity check.  |  |  |  |  |  |  |  |  |
|                      | Select from the following:   |  |  |  |  |  |  |  |  |
| Stop bit             | Appending 1 bit.   |  |  |  |  |  |  |  |  |
|                      | Appending 2 bits.  |  |  |  |  |  |  |  |  |
| Data direction       | MSB or LSB first   |  |  |  |  |  |  |  |  |

Notice: It must be used within the scope of peripheral functional characteristics that meet this condition and meet the electrical characteristics (see data sheret).

### Remark:

### (2) Procedure

Figure 12-74: Initial setup steps for UART transmission

Figure 12-75: Stop steps for UART transmission

www.mcu.com.cn 400 / 624 Rev.1.0.3

Notice: If PER0 is rewritten in the abort setting to stop the clock from being supplied, it is necessary to wait until the communication object stops or the communication is finished to make the initial setting instead of making a restart setting.

www.mcu.com.cn 401 / 624 Rev.1.0.3

### (3) Process flow (single transmit mode)

Figure 12-77: Timing diagram for UART transmission (single transmission mode)

Figure 12-78: Flowchart for UART transmission (single transmission mode) **UART** communication starts relevant initial configuration, refer to the previous SCI initial configuration setting diagram (select transmission completion interrupt) configure transmission data and data count, clear communication completion flag (via software, any configured internal RAM reserved region, transmit data pointer, transmit data communication data count and communication completion flag). main program set to enable interrupt after clear interrupt request flag(IFxx) and enable interrupt release interrupt mask (MKxx). from reserved region read and transmit data and write to SDRmn, update transmit data pointer write data into SDRmn start transmission via writing into **SDRmn** wait transmission completes if transmission completion interrupt occurs, jump to interrupt process program. transmission completion interrupt No interrupt process program transmit next data? Yes if there are data to be transmitted, then read set communication completion flag transmit data from reserved region and write into write data into SDRmn SDRmn, update transmit data pointer. Else, set communication completion flag to 1. **RETURN** No check whether transmission completed via confirming transmission completes? communication completion flag. Yes disable interrupt (mask). main program set STmn bit to 1. communication completed.

Remark: m: unit number (m=0, 1) n: channel number (n=0) q: UART number (q=0, 1).

www.mcu.com.cn 402 / 624 Rev.1.0.3

### (4) Process flow (continuous send mode)

Figure 12-79: Timing diagram for UART transmission (continuous transmission mode)

Note: If the transmit data is written to the SDRmn register during the time when the BFFmn bit of the serial status register mn (SSRmn) is "1" (when valid data is stored in the serial data register mn (SDRmn)), the transmit data is rewritten.

Notice: It is possible to rewrite the MDmn0 bit of the Serial Mode Register mn (SMRmn) even during operation. However, in order to catch the end-of-transmission interrupt for the last data sent, the rewrite must be done before the transmission of the last bit begins.

Remark: m: unit number (m=0, 1) n: channel number (n=0) q: UART number (q=0, 1).

Figure 12-80: Flowchart for UART transmission (continuous transmission ode)

Remark: ① to ⑥ in the figure correspond to ① to ⑥ in "Figure 12-79 Timing Diagram of UART Transmission (Continuous Transmission Mode)".

### 12.7.2 UART reception

UART receive is the operation of this product microcontroller asynchronously receiving data from other devices. The odd number of the 2 channels used by the UART is used for UART reception. However, the SMR registers for odd and even channels need to be set.

Table 12-36: UART reception

| UART                 | UART0 UART1  |                                 |  |  |  |  |
|----------------------|--|---------------------------------|--|--|--|--|
| Target channel       | Channel 1 of SCI0  | Channel 1 of SCI1               |  |  |  |  |
| Pins used            | RxD0   | RxD1                            |  |  |  |  |
| late and             | INTSR0   | INTSR1                          |  |  |  |  |
| Interrupt            | Limited to end-of-transmit interrupts (buffer em   | pty interrupts are prohibited). |  |  |  |  |
| Error interrupt      | INTSRE0  | INTSRE1                         |  |  |  |  |
| Error detection flag | Frame error detection flag (FEFmn) Parity error detection flag (PEFmn) Overflow error detection flag (OVFmn)                   |                                 |  |  |  |  |
| Transfer data length | Data length of 7 bits, 8 bits, 9 bits or 16 bits   |                                 |  |  |  |  |
| Transfer rate        | Max.F <sub>MCK</sub> /6[bps] (SDRmn[15:9]≥2),<br>Min.F <sub>CLK</sub> /(22 <sup>15</sup> 128)[bps]                             |                                 |  |  |  |  |
| Data phase           | Non-reverse output (default: high). Reverse ou   | utput (default: low).           |  |  |  |  |
| Parity bit           | Select from the following.  No parity bit (no parity).  Appending zero check (no parity).  Even parity check  Odd parity check |                                 |  |  |  |  |
| Stop bit             | Appending 1 bit.   |                                 |  |  |  |  |
| Data direction       | MSB or LSB first   |                                 |  |  |  |  |

Notice: It must be used within the scope of peripheral functional characteristics that meet this condition and meet the electrical characteristics (see data sheret).

### Remark:

- 1. F<sub>MCK</sub>: Operation clock frequency of target channel
- 2. F<sub>CLK</sub>: System clock frequency
- 3. m: unit number (m=0, 1) n: channel number (n=1).

### (2) Procedure

Figure 12-82: Initial serup steps for UART reception initial configuration starts release universal serial configure PER0 register communication unit from reset state, start providing clock. configure operational clock configure SPSm register configure SMRmn register configure operational mode..etc. and SMRmr register configure communication format configure SCRmn register configure transmit baud rate configure SDRmn register (configure operation clock(fMCK) scaled transmission clock) via Configure port register and port configure port mode register, set data output of target channel to valid. set SSmn bit of target channel to "1", write into SSm register make Semn to "1" (operation enable state), and wait for start bit detection. initial configuration completes

Notice: At least 4  $F_{MCK}$  clocks must be spaced after setting the RXEmn bit of the SCRmn register to "1" and then set the SSmn bit to "1".

Figure 12-83: Stop steps for UART reception Stop configuration starts if there are ongoing data transmission, No (selection) TSFmn = 0? then wait till transmission completed. (if need urgent stop, then no need to wait). Yes set STmm bit of target channel to 1. (mandatory) write into STm register (SEmn=0: set to operation stop state). stop clock of universal serial communication configure PER0 register (selection) unit, set to reset state finish termination configuration, enter into = configuration ends. next processing.

### Notice:

- 1. At least 4  $F_{MCK}$  clocks must elapse after setting the RXEmn bit of the SCRmn register "1" and then setting the SSmn bit "1".
- 2. If PER0 is rewritten in the abort setting to stop the clock from being supplied, it is necessary to wait until the communication object stops or the communication is finished to make the initial setting instead of making a restart setting.

www.mcu.com.cn 409 / 624 Rev.1.0.3

### (3) Process flow

Figure 12-85: Timing diagram for UART reception

Remark: m: unit number (m=0, 1); n: channel number (n=1); r: channel number (r=n-1); q: UART number (q=0, 1).

www.mcu.com.cn 410 / 624 Rev.1.0.3

Figure 12-86: Flowchart of UART reception **UART** communication starts relevant initial configuration, refer to the SCI initial configuration previous setting diagram (select transmission completion interrupt) configure reciving data storage region and communication data count (via software, any configured internal RAM storage configure receiving data region, receiving data pointer and communication data count). main program set to enable interrupt after clear interrupt enable interrupt request flag(IFxx) and release interrupt mask (MKxx). wait till receiving ends start receiving via detecting start generate interrupt while receiving completes. transmission completion interrupt interrupt process program read received data and write into storage region, incremental counting of received data count, write transmit data to SDRmn update received data pointer. No normal reception? Yes **RETURN** error handling No confirm receiving data count, judge whether receiving completed? receiving completes. Yes main program disable interrupt (mask). write STmn bit to 1. communication completed.

### 12.7.3 Calculation of baud rate

(1) Equation for calculating baud rate

The baud rate for UART (UART0~UART1) communication can be calculated using the following equation.

(Baud rate) = {operating clock frequency ( $F_{MCK}$ ) of the target channel}÷(SDRmn[15:9]+1)÷2[bps]

The operating clock  $(F_{MCK})$  depends on bit15 (CKSmn bit) of the Serial Clock Select Register m (SPSm) and the Serial Mode Register mn (SMRmn).

Notice: It is prohibited to set SDRmn[15:9] of the serial data register mn (SDRmn) to "0000000B" and "0000001B".

Remark: It is 2~127 because the value of SDRmn[15:9] is the value of bit15~9 of SDRmn register (0000010B~1111111B) when using UART.

m: unit number (m=0, 1) n: channel number (n=0, 1).

www.mcu.com.cn 412 / 624 Rev.1.0.3

### (2) Baud rate error when transmitting

The baud rate error during UART (UART0~UART1) communication transmission can be calculated using the following calculation equation, and the baud rate of the sender must be set within the allowable baud rate of the receiver.

(Baud rate error) = (calculated value of baud rate)÷(value of the target baud rate)×100-100[%]

An example of the UART baud rate at F<sub>CLK</sub>=32MHz is shown below.

| UART baud rate     |                                     | F <sub>CLK</sub> =32MHz |                                   |                                 |  |  |  |  |  |  |  |
|--------------------|-------------------------------------|-------------------------|-----------------------------------|---------------------------------|--|--|--|--|--|--|--|

### (3) Allowable range of baud rate when receiving

The baud rate tolerance range for UART (UART0~UART1) communication reception can be calculated using the following equation, and the transmitter baud rate must be set within the the receiver tolerance range.

$$\frac{2 \times k \times Nfr}{2 \times k \times Nfr-k+2} \times Brate$$

$$\frac{2 \times k \times Nfr-k+2}{2 \times k \times Nfr-k+2} \times Brate$$

$$\frac{2 \times k \times Nfr-k+2}{2 \times k \times Nfr-k+2} \times Brate$$

$$\frac{2 \times k \times Nfr-k+2}{2 \times k \times Nfr-k+2} \times Brate$$

Brate: Calculated value of the receiver's baud rate (refer to "12.7.4 (1) Calculation of baud rate")

K: SDRmn[15:9]+1

Nfr: Frame length of 1 data [bit] = (start bit) + (data length) + (parity bit) + (stop bit)

Figure 12-8: Baud rate tolerance range at reception (1 data frame length = 11 bits)

As shown in Figure 12-87, after the start bit is detected, the latch timing of the received data depends on the division ratio set by bit 15 to 9 of the serial data register mn (SDRmn). If the last data (stop bit) catches up with this latch timing, it can be received normally.

Remark: m: unit number (m=0, 1); n: channel number (n=1).

# 12.7.4 Handling steps when an error occurs during UART (UART0~UART1) communication

The processing steps for errors that occur during UART (UART0~UART1) communication are shown in Figure 12-38 and Figure 12-39.

Table 12-38: Processing steps when a parity error or overflow error occurs

| Software operation   | Hardware status   | Remark   |  |  |  |
|--|---|--|--|--|--|
| Read Serial Data Registermn – (SDRmn).                           | The BFFmn bit of the SSRmn register is "0" and channel n is receivable. | This is to prevent an overflow error from occurring if the next reception ends during error handling.                              |  |  |  |
| Read Serial Status Registermn (SSRmn).                           |   | Determines the type of error and reads the value for clearing the error flag.  |  |  |  |
| Write "1" to the serial flag clear trigger register mn (SDIRmn). | Clear the error flag.   | Errors during read operations can only be cleared by writing the read value of the SSRmn register directly to the SDIRmn register. |  |  |  |

Table 12-39: Processing steps when a frame error occurs

| Table 12   | 39. Processing steps when a name e  | 101 000015   |
|--|---|--|
| Software operation   | Hardware status   | Remark   |
| Read Serial Data Registermn - (SDRmn).                               | ► The BFFmn bit of the SSRmn register is "0" and channel n is receivable.   | This is to prevent an overflow error from occurring if the next reception ends during error handling.  |
| Read Serial Status Registermn (SSRmn).                               |   | Determines the type of error and reads the value for clearing the error flag.  |
| Write serial flag clear trigger register—<br>mn (SIRmn).             | Clear the error flag.   | Errors during read operations can only be cleared by writing the read value of the SSRmn register directly to the SDIRmn register.   |
| Set the STmn bit of the serial channel stop register m (STm) to "1". | The SEmn bit of the Serial Channel Enable Status Register m (SEm) is "0" and channel n is in an operation stop state. |  |
| Synchronization with the communicating party.                        |   | Since the start bit is offset, it can be assumed that a framing error has occurred. Therefore, it is necessary to re-synchronize with the communicating party and restart communication. |
| Set the SSmn bit of serial channel start-register m (SSm) to "1".    | The SEmn bit of the serial channel enable status register m (SEm) is "1" and channel n is operational.                |  |

Remark: m: unit number (m=0, 1) n: channel number (n=0, 1).

# 12.8 Operation of LIN communication

### 12.8.1 LIN transmission

UART0 supports LIN communication in UART transmission.

LIN sends channel 0 of unit 0.

Table 12-40: LIN transmission

| UART                      | UART0  | UART1                    |  |  |  |  |
|---------------------------|--|--------------------------|--|--|--|--|
| LIN communication support | Yes  | No                       |  |  |  |  |
| Target channel            | Channel 0 of SCI0  | _                        |  |  |  |  |
| Pins used                 | TxD0 —   |                          |  |  |  |  |
|                           | INTST0   | _                        |  |  |  |  |
| Interrupt                 | Selectable transmission end interrupt (single transmission mode) or buffer empty interrupt (continuous transmission mode). |                          |  |  |  |  |
| Error detection flag      | None   |                          |  |  |  |  |
| Transfer data length      | 8 bits   |                          |  |  |  |  |
| Transfer rate Note        | Max.Fмск/6[bps] (SDR00[15:9]≥2), Min.FcLк/(22  | <sup>215</sup> 128)[bps] |  |  |  |  |
| Data phase                | Non-reverse output (default: high). Reverse output (default: low).   |                          |  |  |  |  |
| Parity check bit          | No parity bits.  |                          |  |  |  |  |
| Stop bit                  | Appending 1 bit.   |                          |  |  |  |  |
| Data direction            | LSB first  |                          |  |  |  |  |

Notice: It must be used within the range of peripheral functional characteristics (refer to the datasheet) that satisfy this condition as well as the electrical characteristics, and 2.4/9.6/19.2 kbps is often used in LIN communications.

### Remark:

- 1. F<sub>MCK</sub>: Operation clock frequency of target channel
- 2. F<sub>CLK</sub>: System clock frequency

www.mcu.com.cn 417 / 624 Rev.1.0.3

LIN is short for Local Interconnect Network, and the communication rate is 1~20Kbps. LIN communication is single-master communication, and a master device can connect up to 15 slave devices.

The LIN slave is used for the control of switches, transmission devices, sensors, etc., which are connected to the main control device through the LIN.

The LIN controls the network which connects CAN (Controller Area Network) and so on.

The LIN bus is a single-line bus, which connects nodes through ISDO9141-compliant transceivers.

According to the LIN protocol, the master device sends a frame with additional baud rate information, and the slave device receives the frame and corrects the baud rate error with the master device. Therefore, if the baud rate error of the slave device is not greater than ±15%, communication can be performed.

A summary of the LIN's send operations is shown in Figure 12-88.

Figure 12-88: Operation of LIN transmission

Note 1: In order to meet the requirements of wake-up signal, set baud rate and transmit "80H" data to correspond.

Note 2: The break field is specified as a 13-bit wide low-level output, so the baud rate used for the main transmission is N[bps]:

(Baud rate for break field) = 9/13×N

Transmit the data of "00H" through this baud rate to generate a break field.

Note 3: Output INTST0 at the end of each data transmission, and also output INTST0 at BF transmission. Remark: The software controls the break between fields.

www.mcu.com.cn 418 / 624 Rev.1.0.3

Figure 12-89: Flowchart of LIN transmission

#### Remark:

- 1. It is limit to situations starting from LIN-bus sleep.
- 2. This is the process that starts by ending the initial set-up of the UART and allowing slave sending.

www.mcu.com.cn 419 / 624 Rev.1.0.3

# 12.8.2 LIN reception

In UART reception, UART0 supports LIN communication.

The LIN receives channel 1 of unit 0.

Table 12-41: LIN reception

| UART                      | UART0   | UART1  |  |  |  |  |  |
|---------------------------|---|--|--|--|--|--|--|
| LIN communication support | Yes   | No   |  |  |  |  |  |
| Target channel            | Channel 1 of SCI0   | _  |  |  |  |  |  |

| Interrupt                 | INTSR0  | _  |  |  |  |  |  |
| Interrupt                 | Limited to end-of-transmit interrupts (buffer empty interrupts are prohibited). |  |  |  |  |  |  |
| Error interrupt           | INTSRE0 —   |  |  |  |  |  |  |
| Error detection flag      | Frame error detection flag (FEF01) Overflow error detection flag (OVF01)        |  |  |  |  |  |  |
| Transfer data length      | 8 bits  |  |  |  |  |  |  |
| Transfer rate Note        | Max.F <sub>MCK</sub> /6[bps] (SDR01[15:9]≥2), Min.F <sub>CLK</sub> /            | /(22 <sup>15</sup> 128)[bps]                                       |  |  |  |  |  |
| Data phase                | Non-reverse output (default: high). Reverse ou                                  | Non-reverse output (default: high). Reverse output (default: low). |  |  |  |  |  |
| Parity check bit          | No parity bits (no parity).   |  |  |  |  |  |  |
| Stop bit                  | Appending 1 bit.  |  |  |  |  |  |  |
| Data direction            | LSB first   |  |  |  |  |  |  |

Notice: It must be used within the scope of peripheral functional characteristics that meet this condition and meet the electrical characteristics (see data sheret).

 $F_{\text{MCK}}$ : Operation clock frequency of target channel  $F_{\text{CLK}}$ : System clock frequency.

Rev.1.0.3 420 / 624 www.mcu.com.cn

A summary of the LIN receive operation is shown in Figure 12-90:

Figure 12-90: LIN reception

The signal processing flow is as follows:

- (1) The wake-up signal is detected by detecting the INTP0 of the pin. When the wake signal is detected, the TM03 is set to measure the pulse width in order to measure the low-level width of BF.
- (2) If the falling edge of BF is detected, TM03 starts to measure the low-level width and captures the rising edge of BF. The BF signal is judged according to the captured value.
- (3) When BF reception ends normally, TM03 must be set as the measurement pulse interval, and the interval of RxD0 signal falling edge of 4 synchronizations (See "5.8.4 Operation as input pulse interval measurement").
- (4) Calculating the baud rate error according to the bit interval of the synchronization section (SF). The baud rate must then be adjusted (reset) after the UART0 run has been paused.
- (5) The checksum segment must be distinguished by software. You must also initialize the UARTO after receiving the checksum segment through the software and set it to the BF receive wait state again.

Figure 12-91: Flowchart of LIN reception LIN Bus signal state and hardware operation. LIN communication starts wake up signal wait for wake up signal frame. NOTE. No frame INTTM03 occurs? Yes channel 3 pulse width INTTM03 accumulated cpature value accumulated 4 times No 4 times completion? modify TM03 to measurement low modify TM03 to measure low voltage width in order to votlage width measure interval field. divide accumulated result by 8, get bit width.

Determine SPS0, SDR00 and SDR01 configuration value calculate baud rate based on this value. perform initial configuration of UART0 based on LIN UART0 initial configuration communication requriements. start UART0 receiving (1->SS01 bit) receiving ID, data and checksum field (process while same ID data reception encounters) all data reception completed? Yes stop UART0(1->ST01 bit) LIN communication ends

Notice: It is only needed in the sleeping state.

The port structure diagram for LIN receive operations is shown in Figure 12-92.

The wake-up signal sent by the LIN master is received through edge detection of the INTP0. The invention can measure the length of the sync field sent by the LIN master and calculate the baud rate error through external event capture operation.

The input source for the received port input (RxD0) can be input to the external interrupt (INTP0) and timer array unit without external connection by port input switching control (ISC0/ISC1).

Figure 12-92: Port structure diagram for LIN receive operation

Remark: ISC0, ISC1: bit0 and bit1 of the Input Switching Control Register (ISC)

Peripheral features for LIN communication operations are summarized as follows:

<Peripheral Features Used>

External interrupt (INTP0): Detection of wake-up signal

Purposes: Detects edges of wake-up signals and the start of communication.

- (1) Channel 3 of General-Purpose Timer Unit: Detection of baud rate error, detection of break field (BF) Purpose: Detects the length of a sync field (SF) and detects baud rate errors by dividing its length by the number of bits (the interval of the RxD0 input edge is measured in capture mode). Measures the width of a low level to determine if it is a break field (BF).
- (2) Channel 0 and Channel 1 (UART0) of General-Purpose Serial Communication Unit 0 (SCI0)

www.mcu.com.cn 424 / 624 Rev.1.0.3

# **Chapter 13 Serial Interface SPI**

### 13.1 Function of serial interface SPI

This product is equipped with a SPI, and has the following two modes.

(1) Run stop mode

This is a mode used when serial transfer is not in progress and reduces power consumption.

(2) 3-wire serial I/O mode

This mode transmits 8-bit or 16-bit data to multiple devices via three lines of serial clock (SCK) and serial data bus (MISO and MOSI).

### 13.2 Structure of serial interface SPI

Figure 13-1: Diagram of serial interface SPI

www.mcu.com.cn 425 / 624 Rev.1.0.3

# 13.3 Registers for controlling serial interface SPI

The serial interface SPI is controlled by the following registers.

- (1) Peripheral enable register 0 (PER0)
- (2) Serial operation mode register (SPIM)
- (3) Serial clock selection register (SPIC)
- (4) Transmit buffer register (SDRO)
- (5) Receive buffer register (SDRI)
- (6) Port mode register (PMxx)
- (7) Port mode control register (PMCxx)
- (8) Port register (Pxx)

# 13.3.1 Peripheral enable register 0 (PER0)

The PER0 register is a register that enables or disables the clock to be supplied to the peripheral hardware.

Reduce power consumption and noise by stopping clocks to hardware that is not in use.

To use the SPI function, SPIEN must be set to "1".

See "4.3.6 Peripheral Enable Registers 0, 1 (PER0, PER1)" for details.

www.mcu.com.cn 426 / 624 Rev.1.0.3

# 13.3.2 SPI operation mode register (SPIM)

SPIM is used to select the mode of operation and control whether the operation is enabled or disabled. SPIM can be set by an 8-bit memory manipulation instruction.

A reset signal is generated to clear the register to 00H.

| Table 13-1: Format of SPI operation mode register (SPIM) |                    |                      |                  |                |                   |                         |               |         |  |  |  |  |  |  |

# 13.3.3 SPI clock selection register (SPIC)

This register specifies the timing of data transmit/receive and sets the serial clock.

It can be set by an 8-bit memory manipulation instruction.

A reset signal is generated to clear this register to 01H.

Table 13-2: Format of SPI clock selection register (SPIC)

|   | Address: | 0x4004240 | 4 After res | set: 00 | ΡΗ  |     | R/W  |      |      |  |

### Notice:

- 1. Write TOPICn is prohibited when SPIE=1 (operation enabled).
- 2. The phase type of the data clock after reset is type 1.

www.mcu.com.cn 428 / 624 Rev.1.0.3

## 13.3.4 Transmit buffer register (SDRO)

This register sets the transmit data.

When bit 7 (SPIE) and bit 6 (TRMD) of the Serial Operation Mode Register (SPIM) are set to 1, transmit/receive is started by writing data to the SDRO.

The serial I/O shift register converts the data in the SDRO from parallel data to serial data and outputs it to the serial output pins.

The SDRO can be written or read by 8-bit or 16-bit memory manipulation instructions.

A reset signal is generated to clear this register to 0000H.

| Table 13-3: Format of transmit buffer register (SDRO) |                    |      |    |    |    |    |   |     |   |   |   |   |   |   |   |   |
|---|--------------------|------|----|----|----|----|---|-----|---|---|---|---|---|---|---|---|
|   | After reset: 0000H |      |    |    |    |    |   | R/W |   |   |   |   |   |   |   |   |
| Symbol  | 15                 | 14   | 13 | 12 | 11 | 10 | 9 | 8   | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| SDRO  |                    | SDRO |    |    |    |    |   |     |   |   |   |   |   |   |   |   |

## 13.3.5 Receive buffer register (SDRI)

This register stores the received data.

If bit 6 (TRMD) of the Serial Operation Mode Register (SPIM) is set to 0, reception is started by reading data from the SDRI.

During reception, data is read from the serial input pins into the SDRI.

The SDRI can be read by 8-bit or 16-bit memory manipulation instructions.

A reset signal is generated to clear this register to 0000H.

# 13.3.6 Registers controlling port functions of SPI pins

When using SPI, you must set the control registers (Port Mode Register (PMxx, PMCxx)) for the port functions that are multiplexed with the SPI input and output pins. For details, refer to "2.3.1 Port Mode Register (PMxx)".

When using the multiplexed port of the SPI pin as an output of SCK/SO/MO, set the bits of each port corresponding to the port mode registers (PMxx, PMCxx) to "0". When the multiplexed port of the SPI pin is used as the input of SCK/SI/MI, the bit of the port mode register (PMxx) corresponding to each port must be set to "1" and the bit of PMCxx must be set to "0". In this case, the bit of the port register (Pxx) can be "0" or "1".

For details, refer to "2.3 Registers for controlling port functions"

# 13.4 Operation of serial interface SPI

In 3-wire serial I/O mode, data is transmitted or received by 8-bit or 16-bit. The data is transmitted or received synchronously with the serial clock.

After communication begins, bit 0 (SPTF) of SPIM is set to 1. When the communication of data is completed, set the communication completion interrupt request flag (SPIIF) and clear SPTF to 0. The next communication is then enabled.

#### Notice:

- 1. When SPTF=1 (during serial communication), access to control registers and data registers are prohibited.
- 2. It must be used within the range that satisfies the SCLK cycle time (T<sub>KCY</sub>) characteristics. Refer to the datasheet for details.

### 13.4.1 Master tramission and reception

If the bit 6 (TRMD) of the serial operation mode register (SPIM) is 1, data can be transmitted or received. When a value is written to the transmit buffer register (SDRO), transmission/reception starts.

### (1) Procedure

Figure 13-2: Initial setup steps for master transmission/reception

www.mcu.com.cn 430 / 624 Rev.1.0.3

Figure 13-3: Stop steps of master transmission/reception

Receive data 1

Receive data 2

register

SDRIF INTSPI

### (2) Process flow

432 / 624 Rev.1.0.3 www.mcu.com.cn

## 13.4.2 Master reception

If bit 6 (TRMD) of the Serial Operation Mode Register (SPIM) is 0, only data can be received. Reception begins when data is read from the receive buffer register (SDRI).

### (1) Procedure

Figure 13-6: Initial setup steps for master reception

www.mcu.com.cn 433 / 624 Rev.1.0.3

Figure 13-7: Stop steps for master reception

Note: In receive-only mode, the SPI transmission is triggered by reading the value of the SDRI register. If the SPI action is not aborted in time, there may be a redundant transmission after the last SDRI read. If you want to avoid the last redundant transmission, you can wait for one SCK cycle after the penultimate read and then turn off the SPIE. The SPI transmission will be aborted after the last data transmission is completed.

www.mcu.com.cn 434 / 624 Rev.1.0.3

### (2) Process flow

## 13.4.3 Slave transmission and reception

If slave mode is selected by bits CKS2-0 of the Serial Clock Selection Register (SPIC) and bit 6 (TRMD) of the Serial Operation Mode Register (SPIM) is 1, the slave transmit/receive mode is entered. When a value is written to the transmit buffer register (SDRO), wait for the clock from the master device to start transmitting/receiving.

### (1) Procedure

Figure 13-9: Initial setup steps for slave transmission and reception

www.mcu.com.cn 436 / 624 Rev.1.0.3

Figure 13-10: Stop steps for slave transmission and reception

www.mcu.com.cn 437 / 624 Rev.1.0.3

### (2) Process flow

www.mcu.com.cn 438 / 624 Rev.1.0.3

## 13.4.4 Slave reception

If slave mode is selected by bit CKS2-0 of the Serial Clock Selection Register (SPIC) and bit 6 (TRMD) of the Serial Operation Mode Register (SPIM) is 0, the slave receive mode is entered. When data is read from the receive buffer register (SDRI), wait for the clock from the master device to begin reception.

#### (1) Procedure

Figure 13-13: Initial setup steps for slave reception

www.mcu.com.cn 439 / 624 Rev.1.0.3

Start of stopping steps Read out the data on the Note penultimate (nth-1) time Set the SPIE bit to "0" and stop Write SPIM register the SPI operation If there is data being NO transmitted, wait for the end of SPTF=0? the transmission. Yes To use the deep sleep mode, stop Set PER0 register the clock of the SPI Unit and set the reset state. End of stopping steps

Figure 13-14: Stop steps for slave reception

Note: In receive-only mode, the SPI transmission is triggered by reading the value of the SDRI register. If the SPI action is not aborted in time, there may be a redundant transmission after the last SDRI read. If you want to avoid the last redundant transmission, you can wait for one SCK cycle after the penultimate read and then turn off the SPIE. The SPI transmission will be aborted after the last data transmission is completed.

### (2) Process flow

# **Chapter 14 Serial Interface IICA**

### 14.1 Function of serial interface IICA

The serial interface IICA has the following 3 modes.

(1) Run stop mode

This is a mode used when serial transfer is not in progress and reduces power consumption.

(2) I<sup>2</sup>C bus mode (supports multi-master)

This mode transmits 8-bit data to multiple devices via two lines of serial clock (SCLAn) and serial data bus (SDAAn). Conforming to the I<sup>2</sup>C-bus format, the master device can generate "start conditions" and "addresses" for the slave device on the serial data bus, Indication of Transfer Direction, Data, and Stop Condition. The slave automatically detects the received status and data through the hardware. This feature simplifies the I<sup>2</sup>C-bus control part of the application.

Because the SCLAn pin and SDAAn pin of the serial interface IICA are used as open-drain outputs, the serial clock line and serial data bus require pull-up resistors.

(3) Wake-up mode

In deep sleep mode, when receiving an extension code or local station address of the autonomous control device, the deep sleep mode can be released by generating an interrupt request signal (INTIICAn). It is set via the WUPn bit of IICA control register n1 (IICCTLn1).

A block diagram of the serial interface IICA is shown in Figure 14-1.

Figure 14-1: Block diagram of serial interface IICA

An example of the structure of a serial bus is shown in Figure 14-2.

Figure 14-2: Example of a serial bus structure for I<sup>2</sup>C bus

Remark: n=0

www.mcu.com.cn 444 / 624 Rev.1.0.3

### 14.2 Structure of serial interface IICA

The serial interface IICA consists of the following hardware.

Table 14-1: Structure of serial interface IICA

| Item              | Structure  |
|-------------------|--|
| Registers         | IICA shift register n (IICAn)                              |
|                   | Slave address register n (SVAn)                            |
|                   | Peripheral enable register 0 (PER0)                        |
|                   | IICA control register n0 (IICCTLn0).                       |
|                   | IICA status register n (IICSn).                            |
|                   | IICA flag register n (IICFn).                              |
| Control registers | IICA control register n1 (IICCTLn1).                       |
| Control registers | IICA low-level width setting register n (IICWLn)           |
|                   | IICA high-Level width setting register n (IICWHn)          |
|                   | Port mode register (PMxx)                                  |
|                   | Port mode control register (PMCxx).                        |
|                   | Port multiplexing function configuration register (PxxCFG) |

#### Remark:

- 1. n=0
- This product can multiplex the IICA input/output pin function to multiple ports. When a port is configured for multiplexing on the IICA pin, the N-channel open-drain output (V<sub>DD</sub>/EV<sub>DD</sub> withstand voltage) mode of the port is designed to automatically open, i.e. the POMxx register does not require user settings.

### (1) IICA shift register n (IICAn)

The IICn register is a register that synchronizes with the serial clock for interconversion of 8-bit serial data and 8-bit parallel data for transmission and reception. Actual sending and receiving can be controlled by reading and writing IICAn registers.

During the wait, the wait is released by writing the IICAn register and the data is transferred. The IICAn registers are set via an 8-bit memory manipulation instruction. After a reset signal is generated, the value of this register becomes "00H".

Table 14-2: Format of IICA shift register n (IICAn)

| Address: | 0x40041B50 | After reset | : 00 | Н |   | R/W |   |   |
|----------|------------|-------------|------|---|---|-----|---|---|
| Symbol   | 7          | 6           | 5    | 4 | 3 | 2   | 1 | 0 |
| IICAn    |            |             |      |   |   |     |   |   |

#### Notice:

- 1. During data transfer, data cannot be written to the IICAn register.
- 2. The IICAn register can only be read and written during the waiting period. Access to the IICAn registers in the communication state is prohibited except during the waiting period. However, in the case of the master device, the IICAn register can be written once after the communication trigger bit (STTn) is set to "1".
- 3. When making an appointment for communication, data must be written to the IICAn register after detecting an interrupt caused by a stop condition.

#### (2) Slave address register n(SVAn)

This is the register that holds the 7-bit local station address {A6,A5,A4,A3,A2,A1,A0} when used as a slave.

The SVAn register is set by the 8-bit memory manipulation instruction. However, when the STDn bit is "1" (start condition detected), it is forbidden to overwrite this register.

After a reset signal is generated, the value of this register becomes "00H".

Table 14-3: Format of slave address register n (SVAn)

| Address: | 0x40041A34 | 4 After res | set: 00 | )H |    | R/W |    |        |
|----------|------------|-------------|---------|----|----|-----|----|--------|
| Symbol   | 7          | 6           | 5       | 4  | 3  | 2   | 1  | 0      |
| SVAn     | A6         | A5          | A4      | A3 | A2 | A1  | A0 | 0 Note |

Note: Bit 0 is fixed to "0".

### (3) SO latch

The SO latch holds the output level of the SDAAn pin

#### (4) Wake-up control circuit

This circuit generates an interrupt request (INTIICAn) when the address value set to the slave address register n(SVAn) is the same as the received address or when an extension code is received.

#### (5) Serial clock counter

During transmission or reception, this counter counts the output or input serial clocks and checks whether 8-bit data transmission and reception are performed.

#### (6) Interrupt request signal generation circuit

This circuit controls the generation of the interrupt request signal (INTIICAn). The I<sup>2</sup>C interrupt request is generated by the following two triggers.

Drop of the 8th or 9th serial clock (set by the WTIMn bit)

Interrupt request (set via SPIEn bit) due to detection of a stop condition.

#### Remark:

- 1. WTIMn bit: bit3 of IICA control register n0 (IICCTLn0)
- 2. SPIEn bit: bit4 of IICA control register n0 (IICCTLn0)

#### (7) Serial clock control circuit

In master mode, this circuit generates the clock output to the SCLAn pin from the sample clock.

#### (8) Serial clock wait control circuit

This circuit controls the wait timing.

(9) Ack generation circuit, stop condition detection circuit, start condition detection circuit, Ack detection circuit

These circuits generate and detect various states.

#### (10) Data hold time correction circuit

This circuit generates a data hold time for the serial clock to drop.

### (11) Start condition generation circuit

If STTn is "1", the circuit generates a start condition.

However, in a state where appointment communication is prohibited (IICRSVn bit =1) and the bus is not released (IICBSYn bit=1), the start condition request is ignored and the STCFn is set to "1".

#### (12) Stop condition generation circuit

If the SPTn bit is "1", the circuit generates a stop condition.

### (13) Bus status detection circuit

This circuit detects whether the bus is released by detecting the start and stop conditions. However, the bus state cannot be detected immediately at the very beginning of operation, so the initial state of the bus state detection circuit must be set by the STCENn bit.

#### Remark:

- 1. STTn bit: Bit1 of IICA control register n0 (IICCTLn0)
- 2. SPTn bit: Bit0 of IICA control register n0 (IICCTLn0)
- 3. IICRSVn bit: Bit0 of IICA flag register n (IICFn)
- 4. IICBSYn bit: Bit6 of IICA flag register n (IICFn)
- 5. STCFn bit: Bit7 of IICA flag register n (IICFn)
- 6. STCENn bit: Bit1 of IICA flag register n (IICFn)
- 7. n=0

## 14.3 Registers for controlling serial interface IICA

The serial interface IICA is controlled by the following registers.

Peripheral enable register 0 (PER0)

IICA control register n0 (IICCTLn0).

IICA flag register n (IICFn).

IICA status register n (IICSn).

IICA control register n1 (IICCTLn1).

IICA low level width setting register n (IICWLn).

IICA high level width setting register n (IICWHn)

Port mode register (PMxx)

Port mode control register (PMCxx)

Port multiplexing function configuration register (PxxCFG)

Port mode register (PMxx)

Port mode control Register (PMCxx)

Port multiplexing function configuration register (PxxCFG)

Note: n=0

## 14.3.1 Peripheral enable register 0 (PER0)

The PER0 register is the register that sets whether to enable or disable the supply of clocks to each peripheral hardware. Reduce power consumption and noise by stopping clocks to hardware that is not in use.

To use the serial interface IICAn, bit4 (IICAEN) must be set to "1".

The PER0 register is set by an 8-bit memory manipulation instruction.

After a reset signal is generated, the value of this register becomes "00H".

Table 14-4: Format of peripheral enable register 0(PER0)

| Address: 0x4 | 0020420 | After res | et: 00H |        |        | R/W    |        |        |
|--------------|---------|-----------|---------|--------|--------|--------|--------|--------|
| Symbol       | 7       | 6         | 5       | 4      | 3      | 2      | 1      | 0      |
| PER0         | RTCEN   | 0         | ADCEN   | IICAEN | SCI1EN | SCI0EN | TM41EN | TM40EN |

| IICAEN | Control of input clocks supplied to serial interface IICA  |
|--------|--|
| 0      | Stop to supply the input clock. The SFR used by the serial interface IICA cannot be written The serial interface IICA is in reset state. |
| 1      | Enable providing input clock The SFRs used by the serial interface IICA can be read and written.   |

Notice: To set the serial interface IICA, the following registers must first be set when the IICAnEN bit is "1". When the IICAnEN bit is "0", the value of the control register of the serial interface IICAn is the initial value, ignoring the write operation (except port multiplexing function configuration register (PxxCFG), port mode registers (PMxx), and port mode control registers (PMCxx).

- (1) IICA control register n0 (IICCTLn0).
- (2) IICA flag register n (IICFn)
- (3) IICA status register n (IICSn)
- (4) IICA control register n1 (IICCTLn1)
- (5) IICA low-level width setting register n (IICWLn)
- (6) IICA high level width setting register n (IICWHn)

Remark: n=0

## 14.3.2 IICA control register n0 (IICCTLn0)

This is a register that enables or stops I<sup>2</sup>C operation, sets the wait sequence, and sets other registers for I<sup>2</sup>C operation.

The IICCTLn0 register is set by an 8-bit memory manipulation instruction. However, the SPIEn bit, WTIMn bit, and ACKEn bit must be set when the IICEn bit is "0" or during a wait period, and these bits can be set at the same time when the IICEn bit is set from "0" to "1".

After a reset signal is generated, the value of this register becomes "00H".

Table 14-5: Format of IICA control register n0(IICCTLn0) (1/4)

| Address: | 0x40041A3 | 30 After res | set: 00 | Н     |       | R/W   |      |      |

| WRELn <sup>Note2,3</sup>                                 | Release waiting  |                          |  |  |  |
|--|--|--------------------------|--|--|--|
| 0  | The wait is not released.  | he wait is not released. |  |  |  |
| 1  | Release wait. Automatically clears after the wait is released.   |                          |  |  |  |
|  | If the WRELn bit (release from wait) is set during the 9th clock wait in the transmit state (TRCn=1), the SDAAn line changes to a high impedance state (TRCn=0). |                          |  |  |  |
| Clear condition (WRELn=0)                                |  | Set condition (WRELn=1)  |  |  |  |
| Automatically cleared after execution.<br>When resetting |  | Set by intructions       |  |  |  |

- Note 1: A reset is performed on the STCFn bit and the IICBSYn bit of the IICA shift register n (IICAn), the IICA flag register n (IICFn), and the CLDn bit and the DADn bit of the IICA control register n1 (IICTLn1).
- Note 2: In the state where the IICEn bit is "0", the signal for this bit is invalid.
- Note 3: The read values for LRELn bits and WRELn bits are always "0".

Notice: If the SCLAn line is high, the SDAAn line is low, and the digital filter is ON (DFCn=1 for the IICCTLn1 register), then enable I<sup>2</sup>C operation (IICEn=1) immediately detects the start condition. At this point, the LRELn bit is set to "1" through the bit memory manipulation instruction after enabling I<sup>2</sup>C to run (IICEn=1).

Table 14-5: Format of IICA control register (IICCTLn0) (2/4)

| WTIMn <sup>Note1</sup>                                     | Control of wait and interrupt requests  |                         |  |  |  |
|--|---|-------------------------|--|--|--|
| 0  | An interrupt request signal is generated on the Master: After outputting 8 clocks, set the clock  | output low to wait.     |  |  |  |
|  | Slave: After inputting 8 clocks, set the clock low<br>An interrupt request signal is generated on the   |                         |  |  |  |
| 1  | Master: After outputting 9 clocks, set the clock output low to wait.  Slave: After inputting 9 clocks, set the clock low and wait for the master.   |                         |  |  |  |
| setting of this bi<br>clock during add<br>the 9th clock af | An interrupt is generated on the falling edge of the 9th clock during the address transfer, regardless of the setting of this bit; the setting of this bit is valid at the end of the address transfer. The master device enters the wait state on the falling edge of the 9th clock during address transmission. A slave device that receives a local station address enters the wait state on the falling edge of the 9th clock after an acknowledge (ACK) is generated, but a slave device that receives an extension code enters the wait state on the falling edge of the 8th clock. |                         |  |  |  |
| Clear condition  | (WTIMn=0)   | Set condition (WTIMn=1) |  |  |  |
| Cleared by intru<br>When resetting                         | ctions.   | Set by intructions      |  |  |  |

| ACKEn <sup>Note1,2</sup>                  | ACK control  |                         |
|---|--|-------------------------|
| 0   | No ack.  |                         |
| 1   | Enables ACK. Sets the SDAAn line low during the 9th clock. |                         |
| Clear condition (ACKEn=0)                 |  | Set condition (ACKEn=1) |
| Cleared by intructions.<br>When resetting |  | Set by intructions      |

Note 1: The signal of this bit is invalid when the ICEn bit is "0". This bit must be set in the meantime.

Note 2: The set value is invalid when it is not an extension code during address transmission. When it is a slave device and the address matches, an ACK is generated regardless of the set value.

Remark: n=0

www.mcu.com.cn 451 / 624 Rev.1.0.3

### Table 14-5: Format of IICA control register (IICCTLn0) (3/4)

| STTn <sup>Note1,2</sup> | Triggering of the start condition  |  |
|-------------------------|--|--|
| 0                       | No start conditions are generated.   |  |
| 1                       | When the bus is released (idle, IICBSYn bit is "0"): If this bit is "1", a start condition (boot as the master device) is generated. When a third party is communicating:  Enables communication reservation function (IICRSVn=0).  Used as a start condition reservation sign. If this bit set to "1", a start condition is automatically generated just after the bus is released.  When the communication reservation function is prohibited (IICRSVn=1).  Even if this bit is "1", the STTn bit is cleared and the STTn clear flag (STCFn) is set to "1" without generating a start condition. Wait status (master device):  Generates a restart condition after the wait is released. |  |

#### Notices on setting timing:

Master reception. Disables setting this bit to "1" during transmission. This bit can only be set to "1" during the waiting period when the ACKEn is "0" and notifying the slavet reception it has completed.

Master transmit: During the Ack, the start conditions may not be generated properly. This bit must be set to "1" during the wait period after the 9th clock is output.

It is prohibited to set "1" at the same time as the stop condition trigger (SPTn).

After setting the STTn bit to "1", it is prohibited to set this bit to "1" again before the clear condition is satisfied.

| Clear condition (STTn=0)                                  | Set condition (STTn=1) |
|---|------------------------|
| Set the STTn bit to "1" in the state where communication  |                        |
| reservation is disabled.                                  |                        |
| When arbitration fails                                    |                        |
| Master device generates start conditions.                 | Set by intructions     |
| Cleared due to the LRELn bit is "1" (Exit Communication). |                        |
| When the IICEn bit is "0" (stop running).                 |                        |
| When resetting  |                        |

Note 1: In the state where the IICEn bit is "0", the signal for this bit is invalid.

Note 2: The read value of the STTn bit is always "0".

#### Remark:

- 1. If bit1 (STTn) is read after setting the data, this bit becomes "0".
- 2. IICRSVn: Bit0 of IICA flag register n (IICFn)
- 3. STCFn: Bit7 of IICA flag register n (IICFn)
- 4. n=0

www.mcu.com.cn 452 / 624 Rev.1.0.3

#### Table 14-5: Format of IICA control register (IICCTLn0) (4/4)

| SPTn <sup>Note1</sup> | Trigger of stop condition                               |  |
|-----------------------|---|--|
| 0                     | No stop conditions are generated.                       |  |
| 1                     | Generates a stop condition (end of transfer as master). |  |

Notices on setting timing:

Master receive: Disables setting this bit to "1" during transmission. This bit can only be set to "1" during the waiting period when ACKEn is at "0" and notifying the slave reception has completed.

Master transmit: During the Ack, the stop conditions may not be generated properly. This bit must be set to "1" during the wait period after the 9th clock is output.

Prohibit setting "1" at the same time as the start condition trigger (STTn).

When the WTIMn bit is "0", it must be noted that if the SPTn bit is set to "1" during the wait period after 8 clocks of output, a stop condition is generated during the high level of the 9th clock after the wait is released. The WTIMn bit must be set from "0" to "1" during the wait period after 8 clocks of output and the SPTn bit must be set to "1" during the wait period after the 9th clock of output.

After setting the SPTn bit to "1", it is prohibited to set this bit to "1" again until the clear condition is satisfied.

| rater cetting the er in sit to 1 , it is premated to cet the sit to | again anti the olear condition to catolica. |
|---|---|
| Clear condition (SPTn=0)  | Set condition (SPTn=1)                      |
| When arbitration fails  |   |
| Cleared automatically when a stop condition is detected.            |   |
| Cleared due to the LRELn bit is "1" (exit communication).           | Set by intructions                          |
| When the IICEn bit is "0" (stop running).                           |   |
| When resetting  |   |

Note 1: The read value of the SPTn bit is always "0".

Notice: If bit3 (TRCn) of the IICA status register n (IICSn) is "1" (transmit state), the wait is released by setting bit5 (WRELn) of the IICCTLn0 register to "1" on the 9th clock, the SDAAn line is set to high impedance after clearing the TRCn bit (receive state). The wait release must be performed by writing to the IICA shift register n when the TRCn bit is "1" (transmit state).

Remark: n=0

www.mcu.com.cn 453 / 624 Rev.1.0.3

## 14.3.3 IICA status register n(IICSn)

This is a register that indicates the I<sup>2</sup>C status.

The IICSn register can only be read by an 8-bit memory manipulation instruction during the STTn bit "1" and waiting. After a reset signal is generated, the value of this register becomes "00H".

Notice: In the allowed address matching wake function (WUPn=1) state in deep sleep mode, reading the IICSn register is prohibited. In the state where the WUPn bit is "1", it has nothing to do with the INTIICAn interrupt request if you change the WUPn bit from "1" to "0" (stop wake-up operation) reflects a change in state until the next start condition or stop condition is detected. Therefore, to use the wake-up function, it is necessary to allow (SPIEn=1) an interrupt due to the detection of a stop condition, and to read the IICSn register after the interrupt is detected.

#### Remark:

- 1. STTn: Bit1 of IICA control register n0 (IICCTLn0)
- 2. WUPn: Bit7 of IICA control register n1 (IICCTLn1)

Table 14-6: Format of IICA status register n (IICSn) (1/3)

| Address: | 0x40041B5 | 51 After res | set: 00 | Н    |      | R     |      |      |

## 14.3.4 IICA flag register n(IICFn)

This is a register that sets the I<sup>2</sup>C operating mode and indicates the status of the I<sup>2</sup>C-bus.

The IICFn register is set by an 8-bit memory manipulation instruction. However, only the STTn clear flag (STCFn) and the I<sup>2</sup>C-bus status flag (IICBSYn) can be read.

The communication appointment function is allowed or disabled by the IICRSVn bit setting, and the initial value of the IICBSYn bit is set by the STCENn bit. Only bit7 (IICEn) = 0) can only write IICRSVn bits and STCENn bits. After allowing operation, only the IICFn registers can be read. After generating a reset signal, the value of this register changes to "00H".

Table 14-7: Format of IICA flag register n(IICFn)

| Α   | ddress: | 0x40041B5 | 52 After res | set: 00 | )H |   | R/W <sup>Note</sup> | Э      |         |
|-----|---------|-----------|--------------|---------|----|---|---------------------|--------|---------|
| S   | ymbol   | 7         | 6            | 5       | 4  | 3 | 2                   | 1      | 0       |
| - 1 | ICFn    | STCFn     | IICBSYn      | 0       | 0  | 0 | 0                   | STCENn | IICRSVn |

| STCFn                     | STTn clear flag   |  |  |
|---------------------------|---|--|--|
| 0                         | Release start conditions.   |  |  |
| 1                         | The STTn flag cannot be cleared while the start condition cannot be issued. |  |  |
| Clear condition (STCFn=0) |   | Set condition (STCFn=1)  |  |
|                           |   | If the STTn bit is cleared to "0" because the start condition cannot be issued in the state where communication reservation is disabled (IICRSVn=1). |  |

| IICBSYn   | I <sup>2</sup> C bus status flag                                      |   |  |
|---|---|---|--|
| 0   | Bus release state (initial state of communication when STCENn=1)      |   |  |
| 1   | us communication state (initial state of communication when STCENn=0) |   |  |
| Clear condition (IICBSYn=0)                     |   | Set condition (IICBSYn=1)   |  |
| IVV/DAD TO A IL ED DIT IS "IL" (STOD ODARSTIAN) |   | When a start condition is detected<br>Sets the IICEn bit when the STCENn bit is "0" |  |

| STCENn  | Initial start enable triggering  |   |  |  |
|---|--|---|--|--|
| 0   | After enabling operation (IICEn=1), a start cond   | ofter enabling operation (IICEn=1), a start condition is allowed to be generated by detecting a stop condition. |  |  |
|   | After enabling operation (IICEn=1), the start condition is allowed to be generated without detecting a stop condition. |   |  |  |
| Clear condition (STCENn=0)  |  | Set condition (STCENn=1)  |  |  |
| Cleared by intructions. When a start condition is detected When resetting |  | Set by intructions  |  |  |

| IICRSVn                                   | Communication reservation function disable bit |                           |  |
|---|--|---------------------------|--|
| 0   | Communication appointments are enabled.        |                           |  |
| 1   | Communication reservations are disabled.       |                           |  |
| Clear condition (IICRSVn=0)               |  | Set condition (IICRSVn=1) |  |
| Cleared by intructions.<br>When resetting |  | Set by intructions        |  |

Note: Bit6 and bit7 are read-only bits.

#### Notice:

- 1. The STCENn bit can only be written when the operation is stopped (IICEn=0).
- 2. If the STCENn bit is "1", the bus is considered to be released (IICBSYn=0) regardless of the actual bus state, so it is necessary to confirm that there is no third party in communication in order to avoid disrupting other communications when the first start condition (STTn=1) is issued.
- 3. IICRSVn can be written only when it is stopped (IICIn=0).

#### Remark:

- 1. STTn: Bit1 of IICA control register n0 (IICCTLn0)
- 2. IICEn: Bit7 of IICA control register n0 (IICCTLn0)

## 14.3.5 IICA control register n1(IICCTLn1)

This is a register used to set the I<sup>2</sup>C operating mode and to detect the status of the SCLAn pin and SDAAn pin.

The IICCTLn1 register is set by an 8-bit memory manipulation instruction. However, only CLDn bits and DADn bits can be read.

With the exception of the WUPn bit, the IICCTLn1 register must be set when I<sup>2</sup>C operation is disabled (bit7 (IICEn) = 0 of the IIC control register n0 (IICCTLn0)).

After a reset signal is generated, the value of this register becomes "00H".

Table 14-8: Format of IICA control register n1 (IICCTLn1) (1/2)

| Address: | 0x40041A3 | 31 After res | set: 00 |      | ,    | R/W <sup>Note</sup> | ž<br>1 |      |
|----------|-----------|--------------|---------|------|------|---------------------|--------|------|
| Symbol   | 7         | 6            | 5       | 4    | 3    | 2                   | 1      | 0    |
| IICCTLn1 | WUPn      | 0            | CLDn    | DADn | SMCn | DFCn                | 0      | PRSn |

| WUPn | Control of address matching wakeup   |
|------|--|
| 0    | Stops the operation of the Address Match Wakeup function in deep sleep mode.   |
| 1    | Enables the operation of the Address Match Wakeup function in deep sleep mode. |

To transfer to deep sleep mode by setting the WUPn bit to "1", at least three FMCK clocks must pass after setting the WUPn bit to "1", and then the deep sleep instruction must be executed (refer to "Figure 14-28 Flow when setting the WUPn bit to "1"). The WUPn bit must be cleared to "0" after the address is matched or the extension code is received. It is possible to participate in subsequent communication by clearing the WUPn bit to "0" (it is necessary to release the wait and write send data after clearing the WUPn bit to "0").

In the state of WUPn bit "1", the interrupt timing when the address is matched or the extension code is received is the same as the interrupt timing when WUPn bit is "0".

(The delay difference of sampling error is generated according to the clock). In addition, when the WUPn bit is "1", even if the SPIEn bit is set to "1", no stop condition interrupt is generated.

| Clear condition (WUPn=0)  | Set condition (WUPn=1)                                  |
|---|---|
| Cleared by instructions (after an address match or reception of | Set by instructions (MSTSn=0, EXCn=0, COIn=0 and STDn=0 |
| an extension code)  | (does not participate in communication)) Note 2         |

Note 1: Bit4 and bit5 are read-only bits.

Note 2: During the period shown below, it is necessary to check the status of the IICA status register n (IICSn) and set it.

### Table 14-8: Format of IICA control register n1 (IICCTLn1) (2/2)

| CLDn   | Level detection of the SCLAn pin (valid only when the IICEn bit is "1"). |                            |  |
|--|--|----------------------------|--|
| 0  | SCLAn pin is detected low.   |                            |  |
| 1  | SCLAn pin is detected high.  |                            |  |
| Clear condition (CLDn=0)   |  | Set condition (CLDn=1)     |  |
| When the SCLAn pin is low When the IICEn bit is "0" (stops operation) When resetting |  | When the SCLAn pin is high |  |

| DADn  | Level detection on the SDAAn pin (valid only when the IICEn bit is "1") |                            |  |
|---|---|----------------------------|--|
| 0   | SDAAn pin is detected as low.   |                            |  |
| 1   | SDAAn pin is detected as high.  |                            |  |
| Clear condition (DADn=0)  |   | Set condition (DADn=1)     |  |
| When the SDAAn pin is low When the IICEn bit is "0" (stops operation). When resetting |   | When the SDAAn pin is high |  |

| SMCn | Switching of operating modes   |
|------|--|
| 0    | Operates in standard mode (maximum transmission rate: 100kbps).  |
| 1    | Operates in Fast Mode (maximum transfer rate: 400kbps) or Enhanced Fast Mode (maximum transfer rate: 1Mbps). |

| DFCn  | Operation control of digital filters |  |  |  |  |  |
|---|--------------------------------------|--|--|--|--|--|
| 0   | Digital filter OFF                   |  |  |  |  |  |
| 1   | Digital filter ON                    |  |  |  |  |  |
| Digital filters must be used in fast mode or enhanced fast mode. Digital filters are used to eliminate noise. |                                      |  |  |  |  |  |
| Whether the DFCn is "1" or "0", the transmission clock is unchanged.  |                                      |  |  |  |  |  |

| PRSn | Control of the operation clock (F <sub>MCK</sub> )       |  |  |  |  |
|------|--|--|--|--|--|
| 0    | Selects F <sub>CLK</sub> (4MHz≤F <sub>CLK</sub> ≤16MHz). |  |  |  |  |
| 1    | Selects F <sub>CLK</sub> /2 (16MHz <f<sub>CLK).</f<sub>  |  |  |  |  |

#### Notice:

- The maximum operating frequency of the IICA running clock (F<sub>MCK</sub>) is 16MHz (Max.). Bit0
  (PRSn) of the IICA control register n1 (IICCTLn1) must be set to "1" only if the F<sub>CLK</sub> exceeds
  16MHz.
- 2. When setting the transmission clock, attention must be paid to the minimum operating frequency of  $F_{CLK}$ . The minimum operating frequency of the  $F_{CLK}$  of the serial interface IICA depends on the mode of operation.

Fast mode: F<sub>CLK</sub>=3.5MHz(Min.)

Enhanced fast mode: F<sub>CLK</sub>=10MHz(Min.)

Standard mode: F<sub>CLK</sub>=1MHz(Min.)

#### Remark:

1. IICEn: Bit7 of IICA control register n0 (IICCTLn0)

2. n=0

www.mcu.com.cn 460 / 624 Rev.1.0.3

## 14.3.6 IICA low-level width setting register n(IICWLn)

This register controls the SCLAn pin signal low-level width (T<sub>LOW</sub>) and SDAAn pin signal from the serial interface IICA output.

The IICWLn register is set by an 8-bit memory manipulation instruction.

The IICWLn register must be set when  $I^2C$  operation is disabled (bit 7 (IICEn) = 0 in IICA control register n0 (IICCTLn0)). The value of this register changes to "FFH" after the reset signal is generated.

For how to set the IICWLn register, refer to "14.4.2 Setting transfer clock via IICWLn and IICWHn registers".

The data retention time is 1/4 of the time set by IICWLn.

Table 14-9 Format of IICA low-level width setting register n (IICWLn)

| Address: | 0x40041A3 | 32 After res | set: FF | H | R/W |   |   |   |
|----------|-----------|--------------|---------|---|-----|---|---|---|
| Symbol   | 7         | 6            | 5       | 4 | 3   | 2 | 1 | 0 |
| IICWLn   | 1         | 1            | 1       | 1 | 1   | 1 | 1 | 1 |

## 14.3.7 IICA high level width setting register n(IICWHn)

This register controls the high-level width of the SCLAn pin signal and the SDAAn pin signal of the serial interface IICA output. The IICWHn register is set by an 8-bit memory manipulation instruction.

The IICWHn register must be set when I<sup>2</sup>C operation is disabled (bit7(IICEn)=0 of IICA control register n0(IICCTLn0)). After a reset signal is generated, the value of this register becomes "FFH".

Table 14-10 Format of high level width setting register n(IICWHn)

| Address: | 0x40041A | 33 After res | set: FF | FH . | R/W |   |   |   |
|----------|----------|--------------|---------|------|-----|---|---|---|
| Symbol   | 7        | 6            | 5       | 4    | 3   | 2 | 1 | 0 |
| IICWHn   | 1        | 1            | 1       | 1    | 1   | 1 | 1 | 1 |

Note 1: For the method of setting the clock transmitted by the main controller, please refer to 14.4.2(1); for how to set the slave IICWLn register and the IICWHn register, refer to 14.4.2(2).

Note 2: n=0

## 14.3.8 Registers controlling port functions of IICA pins

This product can multiplex the pin function of IICAn to multiple ports.

The SCALn pin and SDAAn pin can be configured to the port separately by setting the port multiplexing function configuration registers (SCLAnPCFG and SDAAnPCFG). (n=0)

Set the bits of the Port Mode Control Register (PMCxx) and the Port Mode Register (PMxx) corresponding to these two ports to "0".

When these two ports are configured for multiplexing of the IICA pins, the N-channel open drain output  $(V_{DD}/EV_{DD})$  withstand) mode of the ports is guaranteed by design to turn on automatically, i.e. the POMxx register does not need to be set by the user.

For detailed setting method, see "Chapter 2 Port Function".

### 14.4 Function of I<sup>2</sup>C-bus mode

### 14.4.1 Pin structure

The serial clock pin (SCLAn) and serial data bus pin (SDAAn) are configured as follows.

- (1) SCLAn: input/output pins of the serial clock
  - The outputs of both the master and slave devices are N-channel open-drain outputs, and the inputs are Schmidt inputs.
- (2) SDAAn: input/output multiplexing pins for serial data

The outputs of both the master and slave devices are N-channel open-drain outputs, and the inputs are Schmidt inputs.

Because the outputs of the serial clock line and serial data bus are N-channel open-drain outputs, an external pull-up resistor is required.

slave device VDD master control device **SCLAn SCLAn** clock (clock output) output VDD Vss Vss -(clock clock input input) **SDAAn SDAAn** Data output Data output Vss 77 Vss Data input -Data input

Figure 14-3: Block diagram of pin structure

## 14.4.2 Setting transfer clock via IICWLn and IICWHn registers

(1) Setting transfer clock on master side

Transfer clock = 
$$\frac{F_{MCK}}{IICWL + IICWH + F_{MCK} (T_R + T_F)}$$

At this point, the optimal setpoints for the IICWLn register and the IICWHn register are as follows: (The fractional parts of all setting values are rounded up.)

Fast mode

$$\begin{split} & \text{IICWLn} = \frac{0.52}{\text{transfer clock}} \times \text{F}_{\text{MCK}} \\ & \text{IICWHn} = (\frac{0.48}{\text{transfer clock}} \text{-T}_{\text{R}}\text{-T}_{\text{F}}) \times \text{F}_{\text{MCK}} \end{split}$$

② Standard mode

$$\begin{split} & \text{IICWLn} = \frac{0.47}{\text{transfer clock}} \times \text{F}_{\text{MCK}} \\ & \text{IICWHn} = (\frac{0.53}{\text{transfer clock}} \text{-T}_{\text{R}}\text{-T}_{\text{F}}) \times \text{F}_{\text{MCK}} \end{split}$$

③ Enhanced fast mode

$$\begin{split} & \text{IICWLn} = \frac{0.50}{\text{transfer clock}} \text{ x } \text{F}_{\text{MCK}} \\ & \text{IICWHn} = (\frac{0.50}{\text{transfer clock}} \text{ -T}_{\text{R}}\text{-T}_{\text{F}}) \text{ x } \text{F}_{\text{MCK}} \end{split}$$

(2) Setting IICWLn and IICWHn registers on slave side

(The fractional parts of all setting values are truncated.)

1) Fast mode

② Standard mode

③ Enhanced fast mode

IICWLn=0.50us x 
$$F_{MCK}$$
  
IICWHn=(0.50us- $T_R$ - $T_F$ ) x  $F_{MCK}$ 

#### Notice:

- The maximum operating frequency of the IICA operating clock (FMCK) is 16MHz (Max.). The bit0 (PRSn) of the IICA control register n1 (IICCTLn1) must be set to "1" only when the F<sub>CLK</sub> exceeds 16MHz.
- 2. Note the minimum  $F_{CLK}$  operation frequency when setting the transfer clock. The minimum  $F_{CLK}$  operation frequency for serial interface IICA is determined according to the mode.

Fast mode: F<sub>CLK</sub>=3.5MHz(Min.)

Enhanced fast mode: F<sub>CLK</sub>=10MHz(Min.)

Standard mode: F<sub>CLK</sub>=1MHz(Min.)

3. Calculate the rise time (T<sub>R</sub>) and fall time (T<sub>F</sub>) of the SDAAn and SCLAn signals separately, because they differ depending on the pull-up resistance and wire load.

#### Remark:

- IICWLn: IICA low-level width setting register n; IICWHn: IICA high-level width setting register n
   T<sub>F</sub>: SDAAn and SCLAn signal falling times; T<sub>R</sub>: SDAAn and SCLAn signal rising times
   F<sub>MCK</sub>: IICA operation clock frequency;
- 2. n=0

## 14.5 Definition and control method of I<sup>2</sup>C-bus

The following section describes the I<sup>2</sup>C bus's serial data communication format and the signals used by the I<sup>2</sup>C bus.

The figure below shows the transfer timing for the "start condition", "address", "data", and "stop condition" output via the I<sup>2</sup>C bus's serial data bus.

Figure 14-4: I<sup>2</sup>C bus serial data transfer timing

The master generates start conditions, slave addresses, and stop conditions.

Both the master and slave devices can generate a reply (ACK) (in general, the receiver outputs 8 bits of data). The master device continuously outputs a serial clock (SCLAn). However, the slave can extend the low level of the SCLAn pin during and insert a wait.

www.mcu.com.cn 465 / 624 Rev.1.0.3

### 14.5.1 Start condition

When the SCLAn pin is high, a start condition is generated if the SDAAn pin changes from high to low. The starting conditions for the SCLAn pin and the SDAAn pin are the signals generated when the master device starts serially transmitting to the slave. When used as a slave, the start condition is detected.

Figure 14-5: Start condition

A start condition is output when bit 1 (STTn) of IICA control register n0 (IICCTLn0) is set "1" after a stop condition has been detected (SPDn: Bit 0 of the IICA status register n (IICSn) = 1). When a start condition is detected, bit 1 (STDn) of the IICSn register is set "1".

Remark: n=0

www.mcu.com.cn 466 / 624 Rev.1.0.3

### **14.5.2 Address**

The next 7 bits of data for the start condition are defined as addresses.

The address is 7 bits of data output by the master device in order to select a particular slave device from a plurality of slave devices connected to the bus. Therefore, the slave devices on the bus need to be set to completely different addresses.

The slave detects the start condition through the hardware and checks whether the 7-bit data is the same as the contents of the slave address register n(SVAn). At this time, if the 7-bit data and the value of the SVAn register are the same, the slave is selected to communicate with the master device before the master generates a start or stop condition.

Note: If data other than the local station address or extension code is received while the slave is running, INTIICAn is not generated.

If the 8-bit data consisting of the slave address and the transfer direction described in "14.5.3 Transfer direction specification" is written to the IICA shift register n (IICAn), the address is output. The received address is written to the IICAn register. The slave address is assigned to the higher 7 bits of the IICAn register.

## 14.5.3 Transfer direction specification

In addition to the 7-bit address data, the master device sends 1 bit that specifies the transfer direction.

When this transfer direction specification bit has a value of "0", it indicates that the master device is transmitting data to a slave device. When the transfer direction specification bit has a value of "1", it indicates that the master device is receiving data from a slave device.

Note 1: INTIICAn is not issued if data other than a local address or extension code is received during slave device operation.

## 14.5.4 Acknowledge (ACK)

The serial data status of the sender and receiver can be acknowledged by answer (ACK). The receiver returns a reply each time it receives 8 bits of data.

Typically, the sender receives a reply after sending 8 bits of data. When the receiver returns the reply, it is deemed to have been received normally and continues processing. Bit2 (ACKDn) can pass through the IICA status register n (IICSn). Confirm the detection of the Ack. When the master receives the last data for the received state, a stop condition is generated without returning a reply. When the slave does not return a reply after receiving the data, the master device outputs a stop condition or a restart condition to stop the transmission. The reasons why a reply is not returned are as follows:

- ① Reception was not performed normally.
- 2 The final data item was received.
- 3 The reception side specified by the address does not exist.

To generate ACK, the reception side makes the SDAAn line low at the ninth clock (indicating normal reception).

Automatic generation of ACK is enabled by setting bit 2 (ACKEn) of IICA control register n0 (IICCTLn0) to 1. Bit 3(TRCn) of the IICSn register is set by the data of the eighth bit that follows 7-bit address information. Usually, set the ACKEn bit to 1 for reception (TRCn = 0).

If a slave can receive no more data during reception (TRCn = 0) or does not require the next data item, then the slave must inform the master, by clearing the ACKEn bit to 0, that it will not receive any more data.

When the master does not require the next data item during reception (TRCn = 0), it must clear the ACKEn bit to 0 so that ACK is not generated. In this way, the master informs a slave at the transmission side that it does not require any more data (transmission will be stopped).

When the local address is received, ACK is automatically generated, regardless of the value of the ACKEn bit. When an address other than that of the local address is received, ACK is not generated (NACK). When an extension code is received, ACK is generated if the ACKEn bit is set to 1 in advance. How ACK is generated when data is received differs as follows depending on the setting of the clock stretch timing.

- (1) When 8-clock clock stretch state is selected (bit 3 (WTIMn) of IICCTLn0 register = 0): By setting the ACKEn bit to 1 before releasing the clock stretch state, ACK is generated at the falling edge of the eighth clock of the SCLAn pin.
- (2) When 9-clock clock stretch state is selected (bit 3 (WTIMn) of IICCTLn0 register = 1): ACK is generated by setting the ACKEn bit to 1 in advance.

## 14.5.5 Stop condition

When the SCLAn pin is high, a stop condition is generated if the SDAAn pin changes from low to high. The stop condition is the signal generated when the master ends serial transmission to the slave. When used as a slave, a stop condition is detected.

Figure 14-9: Stop condition

If the bit0 (SPTn) of the IICA control register n0 (IICCTLn0) is set to "1", a stop condition is generated. If a stop condition is detected, set bit0 (SPDn) of the IICA status register n (IICSn) to "1" and generates INTIICAn when bit4 (SPIEn) of the IICCTLn0 register is "1".

Remark: n=0

www.mcu.com.cn 469 / 624 Rev.1.0.3

## 14.5.6 Wait

Notify the other master or slave that the other master or slave is preparing to send/receive data by waiting (waiting status).

Notify the other party that it is in a waiting state by setting the SCLAn pin low. If both the master and slave wait states are released, the next transfer can begin.

Figure 14-10: Wait (1/2)

(1) When master device has a nine-clock wait and slave device has an eight-clock wait (master transmits, slave receives, and ACKEn = 1)

www.mcu.com.cn 470 / 624 Rev.1.0.3

Figure 14-11: Wait (2/2)

(2) When both the master and slave devices are waiting for 9 clocks (master transmits, slave receives, and ACKEn = 1)

generates according to pre-configured ACKEn.

Remark: ACKEn: Bit2 of IICA control register n0 (IICCTLn0)

WRELn: Bit5 of the IICA control register n0 (IICCTLn0)

The wait state is generated automatically by setting bit 3 (WTIMn) of the IICA control register n0 (IICCTLn0). Normally, on the receiving side, if bit5(WRELn) of IICCTLn0 register is "1" or if "FFH" is written to IICA shift register n(IICAn), the wait is released; on the transmitting side, if data is written to IICAn register, the wait is released. On the transmitting side, if data is written to the IICAn register, the wait is released. The master device can also release the wait by the following methods:

Set bit1 (STTn) of the IICCTLn0 register to "1" Set bit0 (SPTn) of the IICCTLn0 register to "1"

## 14.5.7 Method of releasing wait state

In general, I<sup>2</sup>C can release the wait with the following processing.

- (1) Writes data to IICA shift register n (IICAn).
- (2) Sets the bit5 (WRELn) of the IICA control register n0 (IICCTLn0) (wait released).
- (3) Sets the bit1 (STTn) of the IICCTLn0 register (generates a start condition) Note.
- (4) Sets the bit0 (SPTn) of the IICCTLn0 register (generates a stop condition) Note.

Note: Limited to master devices.

If these wait release processes are performed, the I<sup>2</sup>C releases the wait and starts communication again. To send data (including the address) after the release wait, data must be written to the IICAn register.

To receive data after release from waiting or to end sending data, bit 5 (WRELn) of the IICCTLn0 register must be set to "1". To generate a restart condition after releasing the wait, bit 1 (STTn) of the IICCTLn0 register must be set to "1". To generate a stop condition after releasing a wait, bit 0 (SPTn) of the IICCTLn0 register must be set to "1". Only one release process can be performed for one wait.

For example, if data is written to the IICAn register after the wait is released by setting the WRELn bit to "1", the change timing of the SDAAn line may conflict with the write timing of the IICAn register, resulting in the wrong value being output to the SDAAn line. In addition to these processes, if the IICEn bit is cleared to "0" in the case of stopping communication in the middle of the communication, communication is stopped, so that waiting can be released. If the I2C bus state is deadlocked due to noise, if bit 6 (LRELn) of the IICCTLn0 register is set to "1", communication is exited, and thus waiting is released.

#### Remark:

- 1. If the wait release process is performed when the WUPn bit is "1", the wait will not be released.
- 2. n=0

# 14.5.8 Generation timing and waiting control of interrupt requests (INTIICAn)

By setting bit3 (WTIMn) of the IICA control register n0 (IICCTLn0), INTIICAn is generated at the timing shown inTable 14-11 and wait control is performed.

Table 14-11: Generation timing and waiting control of INTIICAn

| WTIMn | Slave operation |                    |                    | Master operation |                |                   |
|-------|-----------------|--------------------|--------------------|------------------|----------------|-------------------|
|       | Address         | Data reception     | Data transmission  | Address          | Data reception | Data transmission |
| 0     | gNote1,2        | 8 <sup>Note2</sup> | 8 <sup>Note2</sup> | 9                | 8              | 8                 |
| 1     | gNote1,2        | 9 <sup>Note2</sup> | 9 <sup>Note2</sup> | 9                | 9              | 9                 |

Note 1: Only when the received address and the set address of the slave address register n(SVAn) are the same, the slave generates an INDICATIONAn signal on the falling edge of the 9th clock and enters a waiting state. At this point, regardless of the bit2 (ACKEn) setting of the IICCTLn0 register, a reply is generated. The slave that receives the extension code generates INTIICAn on the descending edge of the 8th clock. If the addresses are different after restarting, INTIICAn is generated on the falling edge of the 9th clock, but does not enter the waiting state.

Note 2: If the contents of the received address and the slave address register n(SVAn) are different and the extension code is not received, THE INTIICAn is not generated and does not enter the waiting state.

Remark: The numbers in the table represent the number of clocks for a serial clock. Both interrupt request and wait control are synchronized with the falling edge of the serial clock.

#### (1) Address transmission and reception

- ① Slave operation: Regardless of the WTIMn bit, the timing of interruptions and waits is determined according to the conditions in Notes 1 and 2 above.
- ② Master operation: Regardless of the WTIMn bit, the timing of interrupts and waits is generated on the falling edge of the 9th clock.

#### (2) Data reception

Master/slave operation: Determines the timing of interrupts and waits via the WTIMn bit.

#### (3) Data transmission

Master/slave operation: Determines the timing of interrupts and waits via the WTIMn bit.

#### (4) Release method of waiting

There are 4 ways to release from waiting:

- ① Writes data to IICA shift register n (IICAn).
- ② Sets the bit5 (WRELn) of the IICA control register n0 (IICCTLn0) (wait released).
- ③ Sets the bit1 (STTn) of the IICCTLn0 register (generates a start condition) Note.
- ④ Sets the bit0 (SPTn) of the IICCTLn0 register (generates a stop condition) Note.

Note: Limited to master devices.

When you select a wait for 8 clocks (WTIMn=0), you need to decide whether to generate a reply before you release the wait.

#### (5) Detection of stop condition

If a stop condition is detected, INTIICAn is generated (limited to when SPIEn=1).

www.mcu.com.cn 474 / 624 Rev.1.0.3

## 14.5.9 Detection method for address matching

In I<sup>2</sup>C-bus mode, the master device can select a specific slave by sending a slave address. Address matching can be automatically detected by hardware. When the slave address sent by the master device and the set address of the slave address register n(SVAn) are the same or only the extension code is received, an INTIICAn interrupt request is generated.

## 14.5.10 Error detection

In I<sup>2</sup>C-bus mode, because the status of the serial data bus (SDAAn) during the transmission process is taken to the IICA shift register n (IICAn) of the transmitting device, Therefore, it is possible to detect send errors by comparing the IICA data before and after the start of sending. At this point, if the two data are different, it is judged that a sending error has occurred.

Remark: n=0

www.mcu.com.cn 475 / 624 Rev.1.0.3

#### 14.5.11 Extension code

(1) When the high 4 bits of the receiving address are "0000" or "1111", as the received extension code, the extended code receive flag (EXCn) is set to "1", and in the 8th The falling edge of the clock generates an interrupt request (INTIICAn).

Does not affect local station addresses stored in slave address register n (SVAn).

(2) When the SVAn register is set to "11110xx0", if "11110xx0" is sent from the master device via a 10-bit address, the following assertion occurs. However, an interrupt request (INTIICAn) is generated on the falling edge of the 8th clock.

1) High 4 bits data are the same: EXCn=1

2 7 bits of data are the same: COIn=1

#### Remark:

1. EXCn: Bit5 of the IICA status register n

2. COIn: Bit4 of IICA status register n (IICSn)

(3) Since the processing after the interrupt request occurs differs according to the data that follows the extension code, such processing is performed by software. If the extension code is received while a slave device is operating, then the slave device is participating in communication even if its address does not match. For example, after the extension code is received, if you do not wish to operate the target device as a slave device, set bit 6 (LRELn) of IICA control register n0 (IICCTLn0) to 1 to set the standby mode for the next communication operation.

Table 14-12: Bit definitions of major extension codes

| Slave address | R/W bit | Definition  |
|---------------|---------|---|
| 0000000       | 0       | Full call address   |
| 11110xx       | 0       | 10-bit slave address specification (during address authentication)                    |
| 11110xx       | 1       | 10-bit slave address specification (after address match, when read command is issued) |

#### Remark:

- 1. See the I<sup>2</sup>C bus specifications issued by NXP Semiconductors for details of extension codes other than those described above.
- 2. n=0

www.mcu.com.cn 476 / 624 Rev.1.0.3

#### 14.5.12 Arbitration

When multiple master devices generate start conditions at the same time (Set STTn bit to "1" before the STDn bit becomes "1"), the communication of the master device is carried out while adjusting the clock until the data is different. This run is called quorum.

When the arbitration fails, the master device that fails the arbitration places the arbitration failure flag (ALDn) of the IICA status register n (IICSn) to "1" and places the SCLAn Both the line and the SDAAn line are placed in a high impedance state, releasing the bus.

In the event of the next interrupt request (e.g., a stop condition is detected at the 8th or 9th clock), the ALDn bit is "1" via software to detect the failure of the guorum.

For the timing of interrupt requests, please refer to "16.5.8 Generation timing and waiting control of interrupt requests (INTIICAn)".

#### Remark:

- 1. STDn: Bit1 of IICA status register n (IICSn)
- 2. STTn: Bit1 of IICA control register n0 (IICCTLn0)

Figure 14-12: Timing example of arbitration

Table 14-13: Status at the time of arbitration and timing of generation of interrupt requests

| The state in which the arbitration occurred                                | Timing of the generation of interrupt requests                                  |  |  |
|--|---|--|--|
| During address transmission  |   |  |  |
| Reads and writes information after address transmission                    |   |  |  |
| During address extension codes transmission                                |   |  |  |
| Reads and writes information after extension codes transmission            | On the falling edge of the 8th or 9th clock after the byte itransmitted Note1   |  |  |
| During data transmission   |   |  |  |
| During ACK transmission after transmitted data                             |   |  |  |
| Restart condition detected during data transmission                        |   |  |  |
| Stop condition detected during data transmission                           | When generating a stop condition (SPIEn=1) Note2                                |  |  |
| Trying to generate a restart condition, but the data is low.               | On the falling edge of the 8th or 9th clock after the byte is transmitted Note1 |  |  |
| Trying to generate a restart condition, but a stop condition was detected. | When generating a stop condition (SPIEn=1) Note2                                |  |  |
| Trying to generate a stop condition, but the data is low.                  | On the falling edge of the 8th or 9th clock after the byte is transmitted Note1 |  |  |
| Trying to generate a restart condition, but SCLAn is low.                  |   |  |  |

Note 1: The interrupt request is generated on the falling edge of the 9th clock when the WTIMn bit (bit3 of the IICA control register n0 (IICCTLn0)) is "1", and on the falling edge of the 8th clock when the WTIMn bit is "0" and the slave address of the extended code is received.

Note 2: When there is a possibility of arbitration, the SPIEn bit must be "1" when the master is operating. Remark:

- 1. SPIEn: Bit4 of IICA control register n0 (IICTLn0)
- 2. n=0

www.mcu.com.cn 478 / 624 Rev.1.0.3

## 14.5.13 Wake-up function

This is a slave function of I2C, which is the function of generating an interrupt request signal (INTIICAn) when the local station address and extension code are received. The processing efficiency is improved by not generating unwanted INTIICAn signals under different addresses. If a start condition is detected, it enters wake-up standby. Because the master device (where a start condition has already been generated) may also become a slave due to an arbitration failure, it enters wake-up standby at the same time as the address is sent.

To use the wake function in deep sleep mode, you must place the WUPn at "1". The address can be received independent of the operating clock. Even in this case, an interrupt request signal (INTIICAn) is generated when the local station address and extension code are received. After this interrupt is generated, the WUPn bit is cleared to "0" by the instruction and returned to the normal operation.

The flow when the WUPn bit is set to "1" is shown in Figure 14-13, and the flow when the WUPn bit is set to "0" by address matching is shown in Figure 14-14.

www.mcu.com.cn 479 / 624 Rev.1.0.3

Figure 14-14: Flow when the WUPn bit is set to "0" by address matching (including receiving extension codes)

After confirming the operational status of the serial interface IICA, process according to what is to be executed.

In addition to the interrupt request (INTIICAn) generated by the serial interface IICA, the deep sleep mode must be removed through the following procedure.

- (1) Next IIC communication for the operation of the master device: the flow of Fig. 14-15
- (2) Next IIC communication for slave device operation: Return via INTIICAn interrupt: same process as Figure 14-14. Return from an interrupt other than the INTIICAn interrupt: operation must be continued with the WUPn bit set to "1" before the INTIICAn interrupt is generated.

Figure 14-15: Operation as master device after being released from deep sleep mode by an interrupt other than INTIICAn

After confirming the operational status of the serial interface IICA, process according to what is to be executed.

Remark: n=0

www.mcu.com.cn 481 / 624 Rev.1.0.3

## 14.5.14 Communication reservation

- (1) When communication reservation function is enabled (bit0 (IICRSVn)=0 of the IIC flag register n (IICFn)) To perform the next master communication without using the bus, you can send a start condition when the bus is released through a communication reservation. There are two modes under which the bus is not used.
  - ① When arbitration results in neither master nor slave operation
  - ② When an extension code is received and slave operation is disabled (ACK is not returned and the bus was released by setting bit 6 (LRELn) of IICA control register n0 (IICCTLn0) to 1 and saving communication).

If bit 1 (STTn) of the IICCTLn0 register is set to 1 while the bus is not used (after a stop condition is detected), a start condition is automatically generated and wait state is set.

If an address is written to the IICA shift register n (IICAn) after bit 4 (SPIEn) of the IICCTLn0 register was set to 1, and it was detected by generation of an interrupt request signal (INTIICAn) that the bus was released (detection of the stop condition), then the device automatically starts communication as the master. Data written to the IICAn register before the stop condition is detected is invalid.

When the STTn bit has been set to 1, the operation mode (as start condition or as communication reservation) is determined according to the bus status.

- ① Generate a start condition when the bus is released.
- 2 Communication reservation when the bus is not released (standby state)

After the STTn bit is set to "1" and a wait time has elapsed, operation as a communication reservation is confirmed by the MSTSn bit (bit 7 of the IICA status register n (IICSn)).

Waiting times must be ensured by software for the following formula calculations.

Wait time from setting STTn bit to "1" until the MSTSn flag is confirmed: (IICWLn set value+ IICWHn set value + 4) /  $F_{MCK}$  +  $T_F \times 2$ 

#### Remark:

 IICWLn: IICA low-level width setting register n IICWHn: IICA high-level width setting register n T<sub>F</sub>: SDAAn and SCLAn signal falling times

STTn: Bit1 of IICA control register n0 (IICCTLn0)

STDn: Bit1 of IICA status register n (IICSn)
SPDn: Bit0 of IICA status register n (IICSn)

The communication reservation is accepted by the timing sequence shown in Figure 14-17. After bit1 (STDn) of the IICA status register n (IICSn) becomes "1" and before a stop condition is detected, bit1 (STTn) of the IICA control register n0 (IICCTLn0) is set to "1" to make a communication reservation.

Figure 14-17: Timing for accepting communication reservations

The steps for communication reservations are shown in Figure 14-18.

Stop interrupt request Sets STTn flag STTn=1 (communication reservation) Defines that communication reservation is Define communication in effect reservation (defines and sets user flag to any part of RAM) Secures wait time Note 1 by software. Wait (communication reservation)Note 2 Yes Confirmation of communication MSTSn=0? reservation No (Generate start condition) Cancel communication Clear user flag reservation IICAn=xxH Write IICAn Enable interrupt

Figure 14-18: Steps for communication reservations

Note 1: The wait time is calculated as follows. (IICWLn set value+IICWHn set value +4)/ $F_{MCK}+T_F\times 2$ 

Note 2: The communication reservation operation executes a write to the IICA shift register n (IICAn) when a stop condition interrupt request occurs.

#### Remark:

1. STTn: Bit1 of IICA control register n0 (IICCTLn0)

IICWLn: IICA low-level width setting register n IICWHn: IICA high-level width setting register n T<sub>F</sub>: SDAAn and SCLAn signal falling times

F<sub>MCK</sub>: IICA operation clock frequency

2. n=0

(2) When communication reservation function is disabled (bit 0 (IICRSVn) of IICA flag register n (IICFn) = 1)

When bit 1 (STTn) of IICA control register n0 (IICCTLn0) is set to 1 when the bus is not used in a communication during bus communication, this request is rejected and a start condition is not generated. The following two statuses are included in the status where bus is not used.

- ① When arbitration results in neither master nor slave operation
- ② When an extension code is received and slave operation is disabled (ACK is not returned and the bus was released by setting bit 6 (LRELn) of the IICCTLn0 register to 1 and saving communication)

www.mcu.com.cn 484 / 624 Rev.1.0.3

To confirm whether the start condition was generated or request was rejected, check STCFn (bit 7 of the IICFn register). It takes up to 5 cycles of  $F_{MCK}$  until the STCFn bit is set to 1 after setting STTn = 1. Therefore, secure the time by software.

## 14.5.15 Cautions

#### (1) When STCENn = 0

Immediately after  $I^2C$  operation is enabled (IICEn = 1), the bus communication status (IICBSYn = 1) is recognized regardless of the actual bus status. When changing from a mode in which no stop condition has been detected to a master device communication mode, first generate a stop condition to release the bus, then perform master device communication. When using multiple masters, it is not possible to perform master device communication when the bus has not been released (when a stop condition has not been detected). Use the following sequence for generating a stop condition.

- ① Set IICA control register n1 (IICCTLn1).
- ② Set bit 7 (IICEn) of IICA control register n0 (IICCTLn0) to 1.
- 3 Set bit 0 (SPTn) of the IICCTLn0 register to 1.

## (2) When STCENn = 1

Immediately after  $I^2C$  operation is enabled (IICEn = 1), the bus released status (IICBSYn = 0) is recognized regardless of the actual bus status. To generate the first start condition (STTn = 1), it is necessary to confirm that the bus has been released, so as to not disturb other communications.

- (3) If other I<sup>2</sup>C communications are already in progress

  If I<sup>2</sup>C operation is enabled and the device participates in communication already in progress when the SDAAn pin is low and the SCLAn pin is high, the macro of I<sup>2</sup>C recognizes that the SDAAn pin has gone low (detects a start condition). If the value on the bus at this time can be recognized as an extension code, ACK is returned, but this interferes with other I<sup>2</sup>C communications. To avoid this,
  - ① Clear bit 4 (SPIEn) of the IICCTLn0 register to 0 to disable generation of an interrupt request signal (INTIICAn) when the stop condition is detected.
  - Set bit 7 (IICEn) of the IICCTLn0 register to 1 to enable the operation of I<sup>2</sup>C.
  - (3) Wait for detection of the start condition.

start I<sup>2</sup>C in the following sequence.

- Set bit 6 (LRELn) of the IICCTLn0 register to 1 before ACK is returned (4 to 72 cycles of F<sub>MCK</sub> after setting the IICEn bit to 1), to forcibly disable detection.
- (4) Setting the STTn and SPTn bits (bits 1 and 0 of the IICCTLn0 register) again after they are set and before they are cleared to 0 is prohibited.
- (5) When transmission is reserved, set the SPIEn bit (bit 4 of the IICCTLn0 register) to 1 so that an interrupt request is generated when the stop condition is detected. Transfer is started when communication data is written to the IICA shift register n (IICAn) after the interrupt request is generated. Unless the interrupt is generated when the stop condition is detected, the device stops in the wait state because the interrupt request is not generated when communication is started. However, it is not necessary to set the SPIEn bit to 1 when the MSTSn bit (bit 7 of the IICA status register n (IICSn)) is detected by software.

## 14.5.16 Communication operation

The following shows three operation procedures with the flowchart.

(1) Master operation in single master system

The flowchart when using as the master in a single master system is shown below.

This flowchart is broadly divided into the initial settings and communication processing. Execute the initial settings at startup. If communication with the slave is required, prepare the communication and then execute communication processing.

(2) Master operation in multimaster system

In a multi-master system of the I²C bus, it is not possible to judge whether the bus is in the release state or in use during the stage of participating in the communication based on the specifications of the I²C bus. Here, if the data and clock are high for a certain amount of time (1 frame), the bus participates in communication as a release state. This process is roughly divided into "initial settings", "communication waiting" and "communication processing". The processing designated as a slave due to the failure of the arbitration is omitted here, and only the processing used as the master device is omitted. Join the bus after performing the Initial Setup section at startup, and then wait for a communication request from the master device or a designation of the slave device via Communication Wait. The actual communication is the "Communication Processing" section, which supports arbitration with other master devices in addition to data sending and receiving with the slave.

(3) Slave operation

An example of an I<sup>2</sup>C bus slave is shown below.

When used as the slave, operation is started by an interrupt. Execute the initial settings at startup, then wait for the INTIICAn interrupt occurrence (communication waiting). When an INTIICAn interrupt occurs, the communication status is judged and its result is passed as a flag over to the main processing.

By checking the flags, necessary communication processing is performed.

Remark: n=0

www.mcu.com.cn 487 / 624 Rev.1.0.3

#### (1) Master operation of single-master system

Figure 14-19: Master operation of single-master system

Note: I<sup>2</sup>C-bus must be released (SCLAn pins and SDAAn pins are high) depending on the specifications of the product in communication. For example, if the EEPROM is in a state that outputs a low level to

www.mcu.com.cn 488 / 624 Rev.1.0.3

the SDAAn pin, the SCLAn pin must be set to the output port and a clock pulse must be output from the output port before the SDAAn pin is fixed high.

Notice: Conform to the specifications of the product that is communicating, with respect to the transmission and reception formats.

#### (2) Master operation in multi-master system

Figure 14-20: Master operation in multi-master system (1/3)

Note: Confirm that the bus is released (CLDn bit = 1, DADn bit = 1) for a specific period (for example, for a period of one frame). If the SDAAn pin is constantly at low level, decide whether to release the I<sup>2</sup>C bus (SCLAn and SDAAn pins = high level) in conformance with the specifications of the product that is communicating.

Figure 14-22: Master operation in multi-master system (3/3)

#### Notice:

- 1. The format of transmission and reception must conform to the specifications of the product in communication.
- 2. When used as a master device in a multi-master system, the MSTSn bit must be read each time an INTIICAn interrupt occurs to acknowledge the arbitration result.
- 3. When used as a slave device in a multi-master system, the status must be confirmed each time an INTIICAn interrupt occurs by means of the IICA status register n (IICSn) and the IICA flag register n (IICFn) to determine subsequent processing.

Remark: n=0

www.mcu.com.cn 492 / 624 Rev.1.0.3

#### (3) Slave operation

The processing procedure of the slave operation is as follows.

Basically, the slave operation is event-driven. Therefore, processing by the INTIICAn interrupt (processing that must substantially change the operation status such as detection of a stop condition during communication) is necessary.

In the following explanation, it is assumed that the extension code is not supported for data communication. It is also assumed that the INTIICAn interrupt servicing only performs status transition processing, and that actual data communication is performed by the main processing.

Therefore, the following three flags are prepared and pass the flags to the main processing department instead of INTRAICAn for data communication processing.

#### Communication mode flag

This flag indicates the following 2 communication states:

Clear mode: Status in which data communication is not performed

Communication mode: Status in which data communication is performed (from valid address detection to stop condition detection, no detection of ACK from master, address mismatch)

#### ② Ready flag

This flag indicates that data communication is enabled. Its function is the same as the INTIICAn interrupt for ordinary data communication. This flag is set by interrupt handling and cleared by the main processing. Clear this flag by interrupt servicing when communication is started. However, the ready flag is not set by interrupt servicing when the first data is transmitted. Therefore, the first data is transmitted without the flag being cleared (an address match is interpreted as a request for the next data).

#### ③ Communication direction flag

This flag indicates the direction of communication. Its value is the same as the TRCn bit.

#### Remark: n=0

The main processing of the slave operation is explained next.

Start serial interface IICA and wait until communication is enabled. When communication is enabled, execute communication by using the communication mode flag and ready flag (processing of the stop condition and start condition is performed by an interrupt. Here, checks the status by using the flags).

The transmission operation is repeated until the master no longer returns ACK. If ACK is not returned from the master, communication is completed. For reception, the necessary amount of data is received. When communication is completed, ACK is not returned as the next data. After that, the master generates a stop condition or restart condition. Exit from the communication status occurs in this way.

www.mcu.com.cn 493 / 624 Rev.1.0.3

Figure 14-23: Slave operation flowchart (1)

Notice: The format of transmission and reception must conform to the specifications of the product in communication.

An example of the steps for a slave to process via an INTIICAn interrupt is shown below (assuming no extension code is used here). Confirm the status by interrupting THROUGH INTIICAn and perform the following processing.

- ① Communication is stopped if the stop condition is issued.
- ② If the start condition is issued, the address is checked and communication is completed if the address does not match. If the address matches, the communication mode is set, wait is cancelled, and processing returns from the interrupt (the ready flag is cleared).
- 3 For data transmit/receive, only the ready flag is set. Processing returns from the interrupt with the I<sup>2</sup>C bus remaining in the wait state.

Remark: 1 to 3 above correspond to 1 to 3 in "Figure 14-24: Slave operation flowchart (2)".

# 14.6 Timing diagram

When using the I<sup>2</sup>C bus mode, the master device outputs an address via the serial bus to select one of several slave devices as its communication partner. After outputting the slave address, the master device transmits the TRCn bit (bit 3 of the IICA status register n (IICSn)), which specifies the data transfer direction, and then starts serial communication with the slave device. Timing diagrams of the data communication are shown in Figure 14-22 and Figure 14-23.

The IICA shift register n (IICAn)'s shift operation is synchronized with the falling edge of the serial clock (SCLAn). The transmit data is transferred to the SO latch and is output (MSB first) via the SDAAn pin.

Data input via the SDAAn pin is captured into IICAn at the rising edge of SCLAn.

Remark: n=0

Figure 14-25: Example of master to slave communication (Master: selects 9 clocks to wait, slave: selects 9 clocks to wait) (1/4)

## (1) Start Condition ~ Address ~ Data

Note 1: Write data to IICAn, not setting the WRELn bit, in order to cancel a wait state during transmission by a master device.

- Note 2: Make sure that the time between the fall of the SDAAn pin signal and the fall of the SCLAn pin signal is at least 4.0 µs when specifying standard mode and at least 0.6 µs when specifying fast mode.
- Note 3: For releasing wait state during reception of a slave device, write "FFH" to IICAn or set the WRELn bit.

Figure 14-25 shows the descriptions of ① to ⑥ of "(1) Start condition ~ Address ~ Data"

- ① If the master sets the start condition trigger set (STTn=1), the bus data line (SDAAn) drops and the start condition is generated (SDAAn is changed from "1" to "0" by SCLAn=1). Thereafter, if a start condition is detected, the master enters the master communication state (MSTSn=1) and after the hold time elapses the bus clock line drops (SCLAn=0), ending the communication preparation.
  - ② If the master writes address +W (transmit) to IICA shift register n (IICAn), the slave address is sent.
- ③ On the slave, if the receiving address and the local station address (the value of the SVAn) are the same Note, an ACK is sent to the master through hardware. The master detects ACK on the rising edge of the 9th clock (ACKDn=1).
- ④ The master generates an interrupt on the falling edge of the 9th clock (INTIICAn: address send end interrupt). Slaves with the same address enter a waiting state (SCLAn=0) and an interrupt (INTIICAn: address matching interrupt) Note.
  - ⑤ The master writes and transmits data to the IICAn registers, relieving the master of waiting.
  - 6 If the slave releases the wait (WRELn=1), the master begins to transmit data to the slave.

Note: If the sent address and the slave address are different, the slave does not return an ACK (NACK: SDAAn=1) to the master, and does not generate an INTIICAn interrupt (address matching interrupt) or enter a waiting state. However, the master generates ANTIICAn interrupts (address send end interrupts) for both ACK and NAK.

#### Remark:

  - "(1) Start Condition~Address~Data" of Figure 14-25 illustrates steps ①~⑥.
  - "(2) Address~Data~Data" of Figure 14-25 illustrates steps 3~0.
  - "(3) Data~Data~Stop Condition" of Figure 14-25 illustrates steps ⑦~15.
- 2. n=0

www.mcu.com.cn 518 / 624 Rev.1.0.3

Figure 14-25: Example of master to slave communication (Master: selects 9 clocks to wait, slave: selects 9 clocks to wait) (2/4)

#### (2) Address ~ Data ~ Data

Note 1: Write data to IICAn, not setting the WRELn bit, in order to cancel a wait state during transmission by a master device.

Note 2: For releasing wait state during reception of a slave device, write "FFH" to IICAn or set the WRELn bit.

Remark: n=0

Figure 14-25 shows the descriptions of 3 to 0 of "(2) Address~Data~Data"

- ③ On the slave, if the receiving address and the local station address (the value of the SVAn) are the same Note, the ACK is sent to the master through the hardware. The master detects ACK on the rising edge of the 9th clock (ACKDn=1).
- ④ The master generates an interrupt on the falling edge of the 9th clock (INTIICAn: address send end interrupt). Slaves with the same address enter a waiting state (SCLAn=0) and an interrupt (INTIICAn: address matching interrupt) Note.
- ⑤ The master writes and sends data to the IICA shift register n (IICAn) to remove the wait of the main controller.
  - 6 If the slave releases the wait (WRELn=1), the master party begins to transmit data to the slave.
- ⑦ After the data transfer is completed, because the ACKEn bit of the slave is "1", the ACK is sent to the master control through hardware. The master detects ACK on the rising edge of the 9th clock (ACKDn=1).
- ® Both the master and the slave enter a waiting state (SCLAn= 0) on the falling edge of the 9th clock, and both produce interrupts (INTIICAn: Transmit End Interrupt).
- The master controller writes and sends data to the IICAn register to remove the waiting of the main controller.
- ① If the slave reads and receives the data and cancels the wait (WRELn=1), the master party begins to transmit data to the slave.

Note: If the sent address and the slave address are different, the slave does not return an ACK (NACK: SDAAn=1) to the master and does not generate an INTIICAn interrupt (address matching interrupt) or enter a waiting state. However, the master generates ANTIICAn interrupts (address send end interrupts) for both ACK and NAK.

#### Remark:

  - "(1) Start Condition~Address~Data" of Figure 14-25 illustrates steps ①~⑥.
  - "(2) Address~Data~Data" of Figure 14-25 illustrates steps 3~10.
  - "(3) Data~Data~Stop Condition" of Figure 14-25 illustrates steps ⑦~(15).
- 2. n=0

www.mcu.com.cn 520 / 624 Rev.1.0.3

Figure 14-25: Example of master to slave communication (Master: selects 9 clocks to wait, slave: selects 9 clocks to wait) (3/4)

#### (3) Data ~ Data ~ Stop Condition

- Note 1: Write data to IICAn, not setting the WRELn bit, in order to cancel a wait state during transmission by a master device.
- Note 2: After the stop condition is issued, the time from the SCLAn pin signal to generate the stop condition is at least 4.0µs when set to standard mode and at least 0.6µs when set to fast mode.
- Note 3: For releasing wait state during reception of a slave device, write "FFH" to IICAn or set the WRELn bit.

Remark: n=0

Figure 14-25 shows the descriptions of ⑦~(15) of "(3) Data ~ Data ~ Stop":

- ⑦ At the end of the data transfer, because the ACKEn bit of the slave is "1", the ACK is sent to the master through the hardware. The master detects ACK on the rising edge of the 9th clock (ACKDn=1)
- ® Both the master and slave enter a waiting state (SCLAn=0) on the falling edge of the 9th clock, and both produce an interrupt (INTIICAn: end-of-transmit interrupt).
  - The master writes and transmits data to the IICA shift register n (IICAn), relieving the master of waiting.
- ① If the slave reads the received data and dismisses the wait (WRELn=1), the master starts transmitting data to the slave
- ① At the end of the data transfer, the slave (ACKEn=1) sends an ACK to the master through the hardware. The master detects ACK on the rising edge of the 9th clock (ACKDn=1).
- (2) Both the master and slave enter a waiting state (SCLAn=0) on the falling edge of the 9th clock, and both produce an interrupt (INTIICAn: end-of-transmit interrupt).
  - (13) The slave reads the received data and dismisses the wait (WRELn=1).
- (4) If the master sets the stop condition trigger set (SPTn=1), the bus data line (SDAAn=0) is cleared and the bus clock line is set (SCLAn=1), and the bus data line is set after the preparation time for the stop condition is passed (SDAAn=1), Generate a stop condition (SDAAn from "0" to "1" by SCLAn=1).
- (15) If a stop condition is generated, the slave detects the stop condition and generates an interrupt (INTIICAn: Stop condition interrupt).

#### Remark:

- 1. ①~⑤ of Figure 14-25 shows a series of operational steps for data communication via the I<sup>2</sup>C bus.
  - "(1) Start Condition~Address~Data" of Figure 14-25 illustrates steps ①~⑥.
  - "(2) Address~Data~Data" of Figure 14-25 illustrates steps 3~ 10.
  - "(3) Data~Data~Stop Condition" of Figure 14-25 illustrates steps ⑦~(15).
- 2. n=0

Figure 14-25: Example of master to slave communication (Master: selects 9 clocks to wait, slave: selects 9 clocks to wait) (4/4)

#### (4) Data ~ Restart Condition ~ Address

Note 1: Make sure that the time between the rise of the SCLAn pin signal and the generation of the start condition after a restart condition has been issued is at least 4.7 µs when specifying standard mode and at least 0.6 µs when specifying fast mode.

Note 2: For releasing wait state during reception of a slave device, write "FFH" to IICAn or set the WRELn bit.

Remark: n=0

Figure 14-25 shows the operation of "(4) Data ~ Restart Condition ~ Address" as follows. After executing steps 7 and 8, execute <1> to <3> to return to the data sending step of step 3.

- ⑦ After the data transfer is completed, because the ACKEn bit of the slave is "1", the ACK is sent to the master control through hardware. The master detects ACK on the rising edge of the 9th clock (ACKDn=1).
- ® Both the master and the slave enter a waiting state (SCLAn= 0) on the falling edge of the 9th clock, and both produce interrupts (INTIICAn: Transmit End Interrupt).
  - <1> The slave reads and receives the data, and the wait is released (WRELn=1).
  - <2> The start condition trigger is set again by the master device (STTn = 1) and a start condition (i.e. SCLAn =1 changes SDAAn from 1 to 0) is generated once the bus clock line goes high (SCLAn = 1) and the bus data line goes low (SDAAn = 0) after the restart condition setup time has elapsed. When the start condition is subsequently detected, the master device is ready to communicate once the bus clock line goes low (SCLAn = 0) after the hold time has elapsed.
  - <3> The master device writing the address + R/W (transmission) to the IICA shift register (IICAn) enables the slave address to be transmitted.

Remark: n=0

Figure 14-26: Example of slave to master communication

(Master: selects 8 clocks to wait, slave: selects 9 clocks to wait) (1/3)

#### (1) Start Condition ~ Address ~ Data

Note 1: To release the master from waiting during transmit, you must write data to the IICAn instead of setting the WRELn bit.

Note 2: Make sure that the time between the fall of the SDAAn pin signal and the fall of the SCLAn pin signal is at least 4.0 µs when specifying standard mode and at least 0.6 µs when specifying fast mode.

www.mcu.com.cn 525 / 624 Rev.1.0.3

Note 3: To release the slave from waiting during transmission, you must write data to the IICn instead of setting the WRELn bit.

Figure 14-26 shows ① to ⑦ of "(1) Start condition~Address~Data" as follows.

- ① If the master sets the start condition trigger set (STTn=1), the bus data line (SDAAn) drops and the start condition is generated (SDAAn is changed from "1" to "0" by SCLAn=1). Thereafter, if a start condition is detected, the master enters the master communication state (MSTSn=1) and after the hold time elapses the bus clock line drops (SCLAn=0), ending the communication preparation.
  - ② If the master writes address +R (receive) to the IICA shift register n (IICAn), the slave address is sent.
- ③ On the slave, if the receiving address and the local station address (the value of the SVAn) are the same Note, an ACK is sent to the master through hardware. The master detects ACK on the rising edge of the 9th clock (ACKDn=1).
- ④ The master generates an interrupt on the falling edge of the 9th clock (INTIICAn: address send end interrupt). Slaves with the same address enter a waiting state (SCLAn=0) and an interrupt (INTIICAn: address matching interrupt) Note.
  - ⑤ The master changes the wait sequence to the 8th clock (WTIMn=0).
  - (6) The slave writes and sends data to the IICAn register, relieving the slave of the wait.
  - ① The master relieshes the wait (WRELn=1) and begins data transfer from the slave.

Note: If the sent address and the slave address are different, the slave does not return an ACK (NACK: SDAAn=1) to the master and does not generate an INTIICAn interrupt (address matching interrupt) or enter a waiting state. However, the master generates ANTIICAn interrupts (address send end interrupts) for both ACK and NAK.

Figure 14-26: Example of slave to master communication (Master: selects 8 clocks to wait, slave: selects 9 clocks to wait) (2/3)

#### (2) Address ~ Data ~ Data

Note 1: To release the master from waiting during transmit, you must write data to the IICAn instead of setting the WRELn bit.

Note 2: To release the slave from waiting during transmission, you must write data to the IICn instead of setting the WRELn bit.

Figure 14-26 shows 3~(2) of "(2) Address~Data~Data" as follows.

- ③ On the slave, if the receiving address and the local station address (the value of the SVAn) are the same Note, the ACK is sent to the master through the hardware. The master detects ACK on the rising edge of the 9th clock (ACKDn=1).
- ④ The master generates an interrupt on the falling edge of the 9th clock (INTIICAn: address send end interrupt). Slaves with the same address enter a waiting state (SCLAn=0) and an interrupt (INTIICAn: address matching interrupt) Note.
  - ⑤ The master changes the wait sequence to the 8th clock (WTIMn= 0).
  - (b) The slave writes and sends data to the IICA shift register n (IICAn) to release the slave's wait.
  - ① The master relieshes the wait (WRELn=1) and begins data transfer from the slave.
- ® The master enters a waiting state (SCLAn= 0) on the falling edge of the 8th clock and produces an interrupt (INTIICAn: End of Transmission Interrupt). Because the ACKEn bit of the master is "1", the ACK is sent to the slave through the hardware.
  - The master controller reads the received data and cancels the wait (WRELn=1).
  - 1 The slave detects ACK (ACKDn=1) on the rising edge of the 9th clock.
- ① The slave enters a waiting state on the descending edge of the 9th clock (SCLAn = 0) and produces an interrupt (INTIICAn: end-of-transmit interrupt)
- ② If the slave writes and transmits data to the IICAn register, the slave's wait is released and the data transfer from the slave to the master is started.

Note: If the sent address and the slave address are different, the slave does not return an ACK (NACK: SDAAn=1) to the master and does not generate an INTIICAn interrupt (address matching interrupt) or enter a waiting state. However, the master generates ANTIICAn interrupts (address send end interrupts) for both ACK and NAK.

: master device and slave device waits

- Note 1: To release the wait, the IICAn must be set to "FFH" or the WRELn bit must be set.
- Note 2: After the stop condition is issued, the time from the SCLAn pin signal to generate the stop condition is at least 4.0µs when set to standard mode and at least 0.6µs when set to fast mode.
- Note 3: To release the slave from waiting during transmission, you must write data to the IICn instead of setting the WRELn bit.
- Note 4: The TRCn bit is cleared if the wait is released by setting the WRELn bit during the slave transmission.

Figure 14-26 shows 8~(19) of "(3) Data~Data~Stop Condition" as follows.

- ® The master enters a waiting state (SCLAn = 0) on the falling edge of the 8th clock and generates an interrupt (INTIICAn: Transmit End-of-Off). Because the ACKEn bit of the master is "0", the ACK is sent to the slave through the hardware
  - The master reads the received data and dismisses the wait (WRELn=1).
  - 1 The slave detects ACK (ACKDn=1) on the rising edge of the 9th clock.
- ① The slave enters a waiting state on the falling edge of the 9th clock (SCLAn= 0) and generates an interrupt (INTIICAn: transmit end interrupt).
- ② If the slave writes and transmits data to the IICA shift register n (IICAn), the slave's wait is released and the transfer of data from the slave to the master begins.
- (3) The master generates an interrupt (INTIICAn: transmit end interrupt) on the falling edge of the 8th clock and enters a waiting state (SCLAn=0). Because ACK control (ACKEn=1) occurs, the bus data line at this stage becomes low (SDAAn=0)
- (WTIMn=1). If the master relieshes the wait (WRELn=1), the slave detects THEACK (ACKDn=0) on the rising edge of the 9th clock.
- (15) Both the master and slave enter a waiting state (SCLAn=0) on the falling edge of the 9th clock, and both produce an interrupt (INTIICAn: end-of-transmit interrupt).
- (SCLAn=1). (SPTn=1), the bus data cable (SDAAn=0) is cleared and the master's wait is released. After that, the master is on standby until the bus clock line is set in place (SCLAn=1).
- ① The slave stops sending after confirming the NAK, in order to end the communication, the wait is released (WRELn=1). If the slave wait is released, the bus clock line is set in place (SCLAn=1).
- (18) If the master confirms that the bus clock line is set (SCLAn=1), the bus data line is set after the stop condition preparation time has elapsed.
- (9) (SDAAn=1), and then issue a stop condition (SDAAn is changed from "0" to "1" by SCLAn=1). If a stop condition is generated, the slave detects the stop condition and generates an interrupt (INTIICAn: Stop Condition Interrupt).

# **Chapter 15 Linkage Controller EVENTC**

# 15.1 Function of EVENTC

EVENTC links the events output by each peripheral function to each other between the peripheral functions. It can be connected through event chaining without going through the CPU and directly perform collaborative operation between peripheral functions.

EVENTC has the following features:

Depending on the product, event signals for 13 peripheral functions can be linked directly to specified peripheral functions.

Depending on the product, the event signal can be used as the starting source for the operation of 1 of the 4 peripheral functions.

## 15.2 Structure of EVENTC

Block diagram of EVENTC is shown in Figure 15-1.

Figure 15-1: Block diagram of EVENTC

www.mcu.com.cn 531 / 624 Rev.1.0.3

# 15.3 Control registers

The controller registers are shown in Table 15-1.

Table 15-1: Control registers of EVENTC

| Register Name                             | Symbol   |
|---|----------|
| Event output target selection register 00 | ELSELR00 |
| Event output target selection register 01 | ELSELR01 |

# 15.3.1 Output target selection register n(ELSELRn) (n=00~12)

The ELSELRn register links each event signal to the event receiver peripheral function (link target peripheral function) that runs when an event is accepted. You cannot link multiple event inputs to the same event output destination (event receiver). Otherwise, the event receiver peripheral function may operate indefinitely and may not accept the event signal properly. Also, you cannot set the event link occurrence source and event output destination to the same functionality.

The ELSELRn register must be set during periods when the peripheral functions of all event outputs do not generate an event signal.

Table 15-3 lists the correspondence between ELSELRn (n = 00 to 12) registers and peripheral functions, and Table 15-4 lists the correspondence between values set to ELSELRn (n = 00 to 12) registers and operation of link destination peripheral functions at reception.

Note 1: To select the Timer40 channel 0 timer input as the link target peripheral function, you must first set the operating clock of channel 0 to F<sub>CLK</sub> via Timer Clock Select Register 0 (TPS0), set the noise filter on the Tl00 pin to OFF (TNFEN00=0) via Noise Filter Enable Register 1 (NFEN1) and set the timer input used for channel 0 as the event input signal for the link controller via Timer Input Select Register 0 (TIS0).

Note 2: To select the Timer40 channel 1 timer input as the link target peripheral function, you must first set the operating clock of channel 1 to F<sub>CLK</sub> via Timer Clock Select Register 0 (TPS0), set the noise filter of the Tl01 pin to OFF via Noise Filter Enable Register 1 (NFEN1) (TNFEN01=0), and set the timer input used by channel 1 to the event input signal of EVENTC via Timer Input Select Register 0 (TIS0).

# 15.4 Operation of EVENTC

The paths used by the event signals generated by each peripheral function as interrupt requests for the interrupt control circuit and the paths used as EVENTC events are independent of each other. Therefore, each event signal is independent of the interrupt control and can be used as an event signal for the operation of the peripheral function at the event receive side.

The relationship between interrupt processing and EVENTC is shown in Figure 15-2. This diagram shows the relationship for a peripheral function with an interrupt request status flag and an interrupt enable bit (control enable or disable).

The operation of the peripheral function that receives an event via EVENTC is based on the operation of the recipient peripheral function after receiving the event, refer to Table 15-4: Correspondence between values set to ELSELRn (n = 00 to 12) registers and operation of link destination peripheral functions at reception

Figure 15-2: Relationship between interrupt handling and EVENTC

The responses of the peripheral functions that receive the events are shown in Table 15-5.

Event receive Function of event link target Operation after event reception Response target No. EventC events become hardware triggers A/D converter A/D conversion directly for the A/D conversions. Edge detection is performed after 3 or 4 Fclk Timer input of channel 0 of Delay counter input pulse width 2 cycles from the occurrence of an EVENTC Timer40 measure external event counter event. Edge detection is performed after 3 or 4 Fclk Timer input of channel 1 of Delay counter input pulse width 3 cycles from the occurrence of an EVENTC Timer40 measure external event counter event. Becomes a forced truncated state after 2 or 3 Truncated source for EPWM 4 Forced truncation of pulse output EPWM run clock cycles from the occurrence of output control an EVENTC event.

Table 15-5: Response of receiving event peripheral function

Note: Some peripheral functions do not have this feature.

# **Chapter 16 Interrupt Function**

The Cortex-M0+ processor has a built-in nested vector interrupt controller (NVIC), which supports up to 32 interrupt request (IRQ) inputs and one non-maskable interrupt (NMI) input, in addition to multiple internal exceptions.

In this system, the interrupt sources for 32 interrupt request (IRQ) inputs and one non-maskable interrupt (NMI) input are handled. This user's manual only explains the processing for this system. Please refer to the user's manual of Cortex-M0+ processor for the functions of the built-in NVIC of Cortex-M0+ processor.

# 16.1 Types of interrupt functions

There are 2 types of interrupt functions as follows.

- (1) Maskable interrupt
  - This is a mask-controlled interrupt. If the interrupt mask flag register is not opened, the interrupt request will not be responded even if it is generated.
  - It can generate standby release signals, release deep sleep mode and sleep mode.
  - Maskable interrupts are divided into external interrupt requests and internal interrupt requests.
- (2) Non-maskable interrupt
  - This is an interrupt that is not controlled by masking. Once an interrupt request is generated, the CPU must respond to it.

# 16.2 Interrupt sources and structures

Refer to Table 16-1 for a list of interrupt sources.

Table 16-1: List of interrupt sources (1/3)

| Interrupt<br>handling | Interrupt<br>source No. |  | Interrupt resources   |                  | Basic                   |

| Non-<br>maskable | _                    | INTWDT | Watchdog timer interval interruptNote2 | Internal          | (C)   |

Note 1: Basic types (A) $\sim$ (C) correspond to (A) $\sim$ (C) of Figure 16-1, respectively.

Note 2: This is the case when bit7 (WDTINT) of the option byte (000C0H) is set to "1".

## Figure 16-1: Basic structure of interrupt function

### (A) Internal maskable interrupt

## (B) External maskable interrupt (INTPn)

Remark: n=0~3.

## (C) Non-maskable interrupt

Remark: The interrupt request flag IF of a non-maskable interrupt has no physical registers and cannot be used to generate an interrupt request by reading or writing registers on the bus.

www.mcu.com.cn 540 / 624 Rev.1.0.3

**IFmL** 

## 16.3 Registers for controlling interrupt function

Interrupt function is controlled by the following four registers.

- (1) Interrupt request flag register (IF00~IF31)
- (2) Interrupt mask flag register (MK00~MK31)
- (3) External interrupt rising edge enable register (EGP0)
- (4) External interrupt falling edge enable register (EGN0)

### 16.3.1 Interrupt request flag register (IF00~IF31)

- (1) The interrupt request flag is set to "1" by the occurrence of the corresponding interrupt request or execution instruction.
- (2) The interrupt request flag is cleared to "0" by generating a reset signal or by executing an instruction.
- (3) Set IF00L~IF31L registers by an 8-bit memory manipulation instruction
- (4) Or set IF00~IF31 registers by a 32-bit memory manipulation instruction.
- (5) After a reset signal is generated, the value of these registers becomes "0000\_0000H".

#### Table 16-2: Format of interrupt request flag register (IFm) (m=0~31)

```

|          |           |                |        |   |      |      |      |      |
| Address: | 40045B39H | After reset: ( | 00HR/W |   |      |      |      |      |
| Symbol   | 7         | 6              | 5      | 4 | 3    | 2    | 1    | 0    |
| EGN0     | 0         | 0              | 0      | 0 | EGN3 | EGN2 | EGN1 | EGN0 |

| EGPn | EGNn | Active edge selection of INTPn pin (n=0~11) |
|------|------|---|
| 0    | 0    | Disable edge detection.                     |
| 0    | 1    | Falling edge                                |
| 1    | 0    | Rising edge                                 |
| 1    | 1    | Rising and falling edges                    |

The ports corresponding to the EGPn and EGNn bits are shown in Table 16-6.

Table 16-6: Interrupt request signals corresponding to the EGPn and EGNn bits

|           | 1 0                      |       |
|-----------|--------------------------|-------|
| Detection | Interrupt request signal |       |
| EGP0      | EGN0                     | INTP0 |
| EGP1      | EGN1                     | INTP1 |
| EGP2      | EGN2                     | INTP2 |
| EGP3      | EGN3                     | INTP3 |

Notice: If you switch the input port used by the external interrupt function to output mode, an INTPn interrupt may be detected and an INTPn interrupt may be detected. When switching to output mode, the port mode register (PMxx) must be set to "0" after disabling the detection edge (EGPn, EGNn=0, 0).

#### Remark:

- 1. For ports of edge detection, refer to "2.1 Port function".
- 2. n=0~3.

## 16.4 Operation of interrupt handling

## 16.4.1 Maskable interrupt request acknowledgment

If an interrupt request flag is set to "1" and the mask (MK) flag for the interrupt request is cleared to "0", the interrupt request is acknowledged and can be passed to the NVIC.

From the time the interrupt request flag is set to 1, to the time the CPU's IRQ is set to 1, it takes only 1 clock.

### 16.4.2 Non-maskable interrupt request acknowledgment

If a non-maskable interrupt request is generated, the interrupt request flag will be set to "1" and passed directly to the NVIC.

From the time the interrupt request flag is set to 1, to the time the CPU's NMI is set to 1, it takes only 1 clock.

## **Chapter 17 Key Interrupt Function**

The number of channels for key interrupt input varies by product.

## 17.1 Function of key interrupt

A key interrupt (INTKR) can be generated by inputting a falling edge to the key interrupt input pins (KR0~KR7).

Table 17-1: Assignment of key interrupt detection pins

| Key interrupt pin | Key return mode register (KRM) |
|-------------------|--------------------------------|
| KR0               | KRM0                           |
| KR1               | KRM1                           |
| KR2               | KRM2                           |
| KR3               | KRM3                           |
| KR4               | KRM4                           |
| KR5               | KRM5                           |
| KR6               | KRM6                           |
| KR7               | KRM7                           |

## 17.2 Structure of key interrupt

Key interrupts are made up of the following hardware.

Table 17-2: Structure of key interrupts

| Item             | Control register  |
|------------------|---|
| Control register | Key return mode register (KRM) Port mode register (PMx). Port mode control register (PMCx). |

Figure 17-1: Block diagram of key interrupt

Key return mode register

www.mcu.com.cn 547 / 624 Rev.1.0.3

## 17.3 Registers for controlling key interrupts

The key interrupt function is controlled by the following registers.

- (1) Key return mode register (KRM)
- (2) Port mode register (PMx)

## 17.3.1 Key return mode register (KRM)

- (1) The KRM0~KRM7 bits control the KR0~KR7 signals.
- (2) The KRM register is set by an 8-bit memory manipulation instruction.
- (3) After a reset signal is generated, the value of this register becomes "00H".

#### Table 17-3: Format of key return mode register (KRM)

| Address | 6. 40044D37 FI | 00H  | R/VV |      |      |      |      |      |
|---------|----------------|------|------|------|------|------|------|------|
| Symbol  | 7              | 6    | 5    | 4    | 3    | 2    | 1    | 0    |
| KRM     | KRM7           | KRM6 | KRM5 | KRM4 | KRM3 | KRM2 | KRM1 | KRM0 |

| KRMn | Control of key interrupt mode        |
|------|--------------------------------------|
| 0    | No key interrupt signal is detected. |
| 1    | Detects key interrupt signals.       |

#### Notice:

- 1. The internal pull-up resistor can be used by setting the target bit of the pull-up resistor register (PUx) of the key interrupt input pin to "1".
- 2. If the object bit of the KRM register is entered low on the input pin of the key interrupt, an interrupt is generated. To ignore this interrupt, the KRM register must be set after interrupt processing is disabled by the interrupt mask flag. The interrupt request flag must be cleared after waiting for the key interrupt input's low-level width (T<sub>KR</sub>) (see data sheet) to allow interrupt processing.

#### Remark:

- 1. Unused pins in key interrupt mode can be used as normal ports.
- 2. n=0~7.

## 17.3.2 Port mode register (PMx)

- (1) When it is used as the key interrupt input pins (KR0 to KR7), set the PMCxn bit to 0 and the PMxn to 1. The output latches of Pxn at this time may be 0 or 1.
- (2) The PMx register can be set by an 8-bit memory manipulation instruction.
- (3) Reset signal generation sets this register to FFH.
- (4) Use of an on-chip pull-up resistor can be specified in 1-bit units by the pull-up resistor option register (PUx).
- (5) Refer to "2.3.1 Port Mode Register (PMxx)" for the format of the port mode register.

www.mcu.com.cn 548 / 624 Rev.1.0.3

## **Chapter 18 Standby Function**

## 18.1 Standby function

The standby function reduces the operating current of the system, and the following two modes are available.

#### (1) Sleep mode

Sleep mode is the mode in which the CPU is stopped from running the clock. If the high-speed system clock oscillation circuit, high-speed on-chip oscillator, or subsystem clock oscillation circuit is oscillating before the sleep mode is set, the clocks continue to oscillate. Although this mode does not reduce the operating current to the level of deep sleep mode, it is an effective mode for wanting to restart processing immediately through interrupt requests or if you want to run frequently in intermittent operations.

#### (2) Deep sleep mode

Deep sleep mode is a mode that stops the oscillation of the high-speed system clock oscillation circuit and the high-speed on-chip oscillator and stops the entire system. The operating current of the CPU can be greatly reduced.

Because deep sleep mode can be dismissed by interrupt requests, intermittent operations can also be performed. However, in the case of the X1 clock, because the wait time to ensure oscillation stability is required when decommissioning the deep sleep mode, it is necessary to select the sleep mode if you need to start processing immediately through the interrupt request.

In either mode, registers, flags, and data memory are all left set to before standby mode, and the output latches and output buffers of the input/output ports are also maintained.

#### Notice:

- Deep sleep mode is only available when the CPU is running on the main system clock. When
  the CPU is running on the subsystem clock, it cannot be set to deep sleep mode. Sleep mode
  can be used regardless of whether the CPU is running on the main system clock or the
  subsystem clock.
- 2. When moving to deep sleep mode, WFI instructions must be executed after stopping peripheral hardware running in the master system clock.
- 3. To reduce the operating current of the A/D converter, the bit7 (ADCS) of the A/D converter mode register 0 (ADM0) must be placed) and bit0 (ADCE) clear "0", and execute the WFI instruction after stopping the A/D conversion operation.
- 4. The option byte selects whether to continue or stop oscillation of the low-speed internal oscillator in sleep mode or deep sleep mode. For details, please refer to "Chapter 24 Option Bytes".

www.mcu.com.cn 549 / 624 Rev.1.0.3

## 18.2 Sleep mode

### 18.2.1 Setting of sleep mode

When the SLEEPDEEP bit of the SCR register is 0, execute the WFI instruction and enter sleep mode. In sleep mode, the CPU stops operating, but the values of the internal registers are still maintained, and the peripheral modules remain in the state they were in before they entered sleep mode. The status of peripheral modules, vibrators, etc. in sleep mode is shown in Table 18-1.

Sleep mode can be set regardless of whether the CPU clock before setup is a high-speed system clock, a high-speed on-chip oscillator clock, or a sub-system clock.

Remark: When the interrupt mask flag is "0" (enable interrupt processing) and the interrupt request flag is "1" (generating an interrupt request signal), the interrupt request signal is used to decommission sleep mode. Therefore, even if the WFI command is executed in this case, it does not shift to sleep mode.

### 18.2.2 Sleep mode release

The sleep mode can be released by any interrupt or external reset, POR reset, low voltage detection reset, WDT reset, software reset.

#### (1) Released by interrupts

When a non-maskable interrupt is generated and the interrupt is allowed to be accepted, sleep mode is released and the CPU begins processing interrupt services.

Figure 18-1: Release sleep mode by interrupt requests

Note 1: From the generation of the standby release signal to the release of sleep mode, it takes 16 clocks to start executing the interrupt service program.

Note 2: The standby release signal cannot be cleared by itself, and the register must be cleared. Write registers are typically cleared in interrupt service programs.

Remark: Before entering sleep mode, only the maskable bits corresponding to the interrupts expected to be used to release sleep mode should be cleared.

#### (2) Cleared by resets

When a reset signal is generated, the CPU is in reset state and the sleep mode is released. As with a normal reset, the program is executed after transferring to the reset vector address.

Figure

18-2: Release sleep mode by resets

Note 1: For reset processing, please refer to "Chapter 19 Reset Function". For reset processing of poweron reset (POR) and voltage detection (LVD), refer to "Chapter 20 Power-on Reset Circuit".

## 18.3 Deep sleep mode

### 18.3.1 Setting of deep sleep mode

When the SLEEPDEEP bit of the SCR register is 1, the WFI instruction is executed and deep sleep mode is entered. In this mode, the CPU, most of the peripheral modules, and the vibrator operation stops. However, the values of the CPU internal registers, the RAM data, the peripheral modules, the state of the I/O are maintained. The operating status of the peripheral module and the vibrator in deep sleep mode is shown in Table 18-2.

The deep sleep mode can only be set if the CPU clock before setting is as the main system clock.

Remark: When the interrupt mask flag is "0" (allows interrupt processing) and the interrupt request flag is "1" (generating an interrupt request signal), the interrupt request signal is used to dismiss deep sleep mode. Therefore, if the WFI instruction is executed in this case, it is dismissed as soon as it enters deep sleep mode. Returns to run mode after executing the WFI instruction and after a deep sleep mode release time has elapsed.

### 18.3.2 Deep sleep mode release

The deep sleep mode can be released by the following two sources.

(1) Released by non-maskable interrupt requests

If a non-maskable interrupt request occurs, deep sleep mode is released. After the oscillation stabilization time, if the interrupt is allowed to be accepted, the vector interrupt is processed. If the interrupt acceptance is disabled, the next address is executed.

Figure 18-3: Release deep sleep mode by interrupt requests

Note 1: Standby release signal: For details of the standby release signal, please refer to "Figure 16-1 Basic structure of interrupt function".

Note 2: Deep sleep release preparation time.

- When the CPU clock is a high-speed on-chip oscillation clock or an external clock input before entering deep sleep mode: at least 20us.
- When entering deep sleep mode before the CPU clock is a high-speed system clock (X1 oscillation): at least 20us and a longer time in the oscillation settling time (set by OSTS).

Note 3: Wait: 14 clocks are required from when the time CPU.IRQ is valid to the interrupt service program starts.

#### Notice:

- 1. Before entering sleep mode, only the mask bits corresponding to the interrupts expected to be used to release sleep mode should be cleared to zero.
- When the CPU is running at high speed system clock (X1 oscillation) and to shorten the
  oscillation stabilization time after the deep sleep mode is released, the CPU clock must be
  temporarily switched to the high-speed on-chip oscillator clock before the WFI instruction is
  executed.
- 3. The oscillation accuracy of the high-speed on-chip oscillator clock varies steadily depending on temperature conditions and during deep sleep mode.

#### (2) Released by generating reset signals

The deep sleep mode is released by generating a reset signal. Then, as with a normal reset, the program is executed after transferring to the reset vector address.

**Figure** 

18-4: Release deep sleep mode by resetting

Note 1: For reset processing, see "Chapter 19 Reset Function". For reset processing of power-on reset (POR) and voltage detection (LVD), see "Chapter 21 Power-on Reset Circuit".

## 18.4 Deep sleep mode with partial power down

### 18.4.1 Setting of deep sleep mode with partial power down

The deep sleep mode with partial power loss is a deep sleep mode that further saves power consumption by turning off some peripheral power supplies on the basis of deep sleep mode. Enter the partial power-down deep sleep mode needs to configure the PWDNEEN bit of the PMUCTL register, the control bit is written to the power supply mode control protection register (PMUKEY) protection, when the deep sleep mode of partial power down requires reinitialization of the power-down periphery before it can re-operate normally, please refer to Table 18-3 The operation status in the deep sleep mode of the partial power-down is required for details.

When the SCR register has a SLEEPDEEP bit of 1 and the PMUCTL register has a PWDNEEN bit of 1, executing the WFI command can enter a partially powered-down deep sleep mode. In this mode, the CPU and the transmitter stop functioning, and most peripheral modules are powered off. However, the value of the CPU's internal registers, RAM data, the state of the I/O is maintained. The operating status of the peripheral module and the oscillator in the deep sleep mode of partial power failure is shown in Table 18-3.

A partially powered-down deep sleep mode can only be set if the CPU clock before setting is the main system clock. The PWDNEEN bit of the PMUCTL register is controlled with reference to the section 4.3.11 Power Supply Mode Control Protection Register (PMUKEY) and the 4.3.12 Power Supply Mode Control Register (PMUCTL).

PMUKEY=0x192A;

PMUKEY=0x3E4F;

PMUCTL=1;

SCB->SCR |= 0x04;

WFI();

Deep sleep mode with partial power down

Figure 18-5: Flowchart of entering deep sleep mode with partial power down

www.mcu.com.cn 557 / 624 Rev.1.0.3

Remark: When the interrupt mask flag is "0" (interrupt processing is allowed) and the interrupt request flag is "1" (interrupt request signal is generated), the interrupt request signal is used to release the deep sleep mode. Therefore, if the WFI instruction is executed in this case, it is released as soon as the deep sleep mode is entered, and the partial power-down mode is not entered in this case. The WFI command is executed and returns to the operation mode after the deep sleep mode release time.

www.mcu.com.cn 558 / 624 Rev.1.0.3

#### Remark:

- 1. Operation stopped: Operation is automatically stopped before switching to the deep sleep mode with partial power down.
- 2. Operation disabled: Operation is stopped before switching to the deep sleep mode with partial power down
- 3. Power supply maintained: Maintains module power supply after switching to the deep sleep mode with partial power down.
- 4. Power supply stopped: After transferring to a deep sleep mode with partial power down, the power supply to the module is stopped, and the module needs to be re-initialized after the mode is released.
- 5. F<sub>IH</sub>: High-speed on-chip oscillator clock F<sub>IL</sub>: Low-speed on-chip oscillator clock

F<sub>X</sub>: X1 clock F<sub>EX</sub>: External main system clock

F<sub>XT</sub>: XT1 clock F<sub>EXS</sub>: External subsystem clock

### 18.4.2 Release deep sleep mode with partial power down

Release the deep sleep mode with partial power down by the following 2 methods.

(1) Release deep sleep mode with partial power-down via interrupt requests If INTP0-3, INTKR, INTRTC, INTIT, INTLVI and INTWDT interrupt requests are generated, the deep sleep mode with partial power down can be released. After the oscillation stabilization time, if it is in the state of enabling interrupt reception, it will process the vector interrupt. If the interrupt is disabled, the next address instruction is executed.

Figure 18-6: Release deep sleep mode by interrupting requests

- Note 1: Standby release signals: Interrupt request signals for INTP0-3, INTKR, INTRTC, INTIT, INTLVI, and INTWDT.
- Note 2: When the deep sleep state of partial power-down is ready to be released, it is necessary to reinitialize the peripheral functions in order to ensure that the program continues to run normally.
- Note 3: Before entering the deep sleep mode with partial power-down, only the mask bit corresponding to the interrupt that is expected to be used to release the sleep mode should be cleared to zero.
- (2) Release by generating a reset signal

The deep sleep mode with partial power-down is released by generating a reset signal. Then, as with a normal reset, the program is executed after switching to the reset vector address.

Figure 18-7: Release deep sleep mode with partial power-down by resetting

Note 1: For reset processing, refer to "Chapter 19 Reset Function". Refer to "Chapter 20 Power-On Reset Circuit" and "Chapter 21 Voltage Detection Circuit" for reset processing of the power-on reset (POR) circuit and voltage detection (LVD) circuit.

www.mcu.com.cn 560 / 624 Rev.1.0.3

## **Chapter 19 Reset Function**

The following six operations are available to generate a reset signal.

- (1) External reset input via RESETB pin.
- (2) Internal reset is generated by programmed runaway detection of the watchdog timer.
- (3) Internal reset is generated by comparison of the power supply voltage and the detection voltage of the power-on reset (POR) circuit.
- (4) An internal reset is generated by comparing the supply voltage of the voltage detection circuit (LVD) with the detection voltage.
- (5) An internal reset is generated by setting the system reset request register bit (AIRCR.SYSRESETREQ) to 1.
- (6) Internal reset due to illegal memory access.

Internal reset is the same as external reset, and after generating a reset signal, the program is executed starting from the user-defined program start address. When a low level is supplied to the RESETB pin, or a program runaway is detected by the watchdog timer, or a voltage is detected in the POR and LVD circuits, or the system reset request bit is set, or an illegal memory access occurs, a reset is generated and the hardware changes to the state shown in Table 19-1.

#### Notice:

- 1. When performing an external reset, the RESETB pin must be held low for at least 10us. If an external reset is performed while the supply voltage is rising, the power must be turned on after supplying a low level to the RESETB pin, and must be held low for at least 10us over the operating voltage range shown in the AC Characteristics of the User's Manual, and then be supplied with a high level.
- 2. Stop oscillating of X1 clock, XT1 clock, high-speed on-chip oscillator clock, and low-speed internal oscillator clock during the reset signal. The inputs to the external master system clock and the external subsystem clock are invalid.
- 3. If a reset occurs, each SFR is initialized so that the pins change to the following states.
  - P00: Low during external reset or POR reset, high during other reset periods and during normal operation.
  - 2 P20,P21,P36,P37: High during external reset or POR reset. High during other resets and after receiving a reset (connect internal pull-up resistor).
  - 3 Other ports: High impedance during reset and after receiving reset.

www.mcu.com.cn 561 / 624 Rev.1.0.3

Figure 19-1: Block diagram of reset function

#### Remark:

- 1. An internal reset of the LVD circuit does not reset the LVD circuit.
- 2. LVIM: Voltage detection register
- 3. LVIS: Voltage detection level register

When the RESETB pin is input low, a reset is generated. The reset state is then released if the RESETB lead is entered high and the program begins with a high-speed on-chip oscillator clock after the reset process is complete.

Figure 19-2: Timing of RESETB input

For reset caused by overflow of the watchdog timer, setting of the system reset request bit, or detection of illegal memory access, the reset state is automatically released, and program execution starts with the high-speed on-chip oscillator clock after the reset processing is completed.

Figure 19-3: Reset timing due to watchdog timer overflow, system reset request bit setting, or illegal memory

Note 1: P00,P20,P20,P36,P37 change to the following states.

① P00: Low during external reset or POR reset, high during other resets and during normal operation.

www.mcu.com.cn 563 / 624 Rev.1.0.3

② P20,P21,P36,P37: High impedance during external reset or POR reset. High during other resets and after receiving a reset (internal pull-up resistor connected).

Remark: Reset is performed when an internal reset occurs, and the watchdog timer is no exception.

For the reset generated by the voltage detection of the POR circuit and the LVD circuit, if  $V_{DD} \geqslant V_{POR}$  or  $V_{DD} \geqslant V_{LVD}$  is satisfied after the reset, the reset state is released and the program is executed with a high-speed on-chip oscillator clock after the reset is processed. For details, please refer to "Chapter 20 Power-on Reset Circuit" and "Chapter 21 Voltage Detection Circuit".

#### Remark:

- 1. V<sub>POR</sub>: POR supply voltage rising detection voltage
- 2. V<sub>LVD</sub>: LVD detection voltage

## 19.1 Registers for confirming the reset source

## 19.1.1 Reset control flag register (RESF)

The CMS32L032 microcontroller has multiple internal reset generation sources. The Reset Control Flag register (RESF) holds the reset source where the reset request occurs. The RESF register can be read by an 8-bit memory manipulation instruction.

The SYSRF, WDTRF, IAWRF, LVIRF flags are cleared by inputting RESETB, resetting the power-on reset (POR) circuit, and reading the RESF register. To determine the reset source, the value of the RESF register must be saved to any RAM and then determined by its RAM value.

Table 19-2: Format of reset control flag register (RESF)

| Address: 40020440H |       | After reset: | undefined <sup>Note</sup> | R     |   |   |       |       |
|--------------------|-------|--------------|---------------------------|-------|---|---|-------|-------|
| Symbol             | 7     | 6            | 5                         | 4     | 3 | 2 | 1     | 0     |
| RESF               | SYSRF | 0            | 0                         | WDTRF | 0 | 0 | IAWRF | LVIRF |

| SYSRF | Internal reset request resulting from the system reset request bit being set |
|-------|--|
| 0     | No internal reset request is generated or the RESF register is cleared.      |
| 1     | Generates an internal reset request.   |

| WDTRF | Internal reset request generated by the watchdog timer (WDT)            |
|-------|---|
| 0     | No internal reset request is generated or the RESF register is cleared. |
| 1     | Generates an internal reset request.                                    |

| IAWRF | Access to internal reset requests generated by illegal memory           |
|-------|---|
| 0     | No internal reset request is generated or the RESF register is cleared. |
| 1     | Generates an internal reset request.                                    |

| LVIRF | Internal reset request generated by the voltage detection circuit (LVD) |
|-------|---|
| 0     | No internal reset request is generated or the RESF register is cleared. |
| 1     | Generates an internal reset request.                                    |

Note: It varies depending on the reset source, please refer to Table 19-3.

The status of the RESF register when a reset request occurs is shown in Table 19-3.

| •                | •                          |                    |
|------------------|----------------------------|--------------------|
| Table 19-3: RESF | register status when a re- | set request occurs |

| SYSRF          |                | Cleared to "0" | Set to "1"  | Held                         | Held   | Held                         |
| WDTRF          | Cleared to "0" |                |   | Set to "1"                   |  |                              |
| IAWRF          | Cleared to 0   |                | Held  |                              | Set to "1"   |                              |
| LVIRF          |                |                |   |                              | Held   | Set to "1"                   |

The confirmation steps for resetting the source are shown in Figure 19-4.

Remark: The flow described above is an example of the procedure for checking.

## **Chapter 20 Power-On Reset Circuit**

## 20.1 Function of power-on reset circuit

The power-on reset circuit (POR) has the following functions.

- (1) Generates internal reset signal at power on. The reset signal is released when the supply voltage (V<sub>DD</sub>) exceeds the detection voltage (V<sub>POR</sub>). Note that the reset state must be retained until the operating voltage becomes in the range defined in AC Characteristics. This is done by utilizing the voltage detection circuit or controlling the externally input reset signal.
- (2) Compares supply voltage (V<sub>DD</sub>) and detection voltage (V<sub>PDR</sub>), generates internal reset signal when V<sub>DD</sub> < V<sub>PDR</sub>. Note that, after power is supplied, this should be placed in the deep sleep mode, or in the reset state by utilizing the voltage detection circuit or externally input reset signal, before the operation voltage falls below the range defined in AC Characteristics. When restarting the operation, make sure that the operation voltage has returned within the range of operation.

#### Remark:

- 1. When the power-on reset circuit generates an internal reset signal, the reset control flag register (RESF) is cleared to "00H".
- 2. The CMS32L032 microcontroller incorporates multiple hardware functions that generate an internal reset signal. A flag that indicates the reset source is located in the reset control flag register (RESF) for when an internal reset signal is generated by the watchdog timer (WDT), voltage-detector (LVD), system reset request bit setting, or illegal-memory access. The RESF register is not cleared to 00H and the flag is set to 1 when an internal reset signal is generated by the watchdog timer (WDT), voltage-detector (LVD), system reset request bit setting, or illegal-memory access. For details of RESF register, refer to "Chapter 19 Reset Function".
- 3. V<sub>POR</sub>: POR power supply rise detection voltage; V<sub>PDR</sub>: POR power supply fall detection voltage
- 4. For details, refer to the POR circuit characteristics in the data sheet.

## 20.2 Structure of power-on reset circuit

The block diagram of the power-on reset circuit is shown in Figure 20-1.

Figure 20-1: Block diagram of power-on reset circuit

## 20.3 Operation of power-on reset circuit

The timing of the internal reset signal generation for the power-on reset circuit and the voltage detection circuit is shown below.

Figure 20-2: Timing of internal reset signal generation for power-on reset circuit and voltage detection circuit (1/3)

(1) When the externally input reset signal on the RESETB pin is used

- Note 1: The internal reset processing time includes the oscillation accuracy stabilization wait time of the high-speed on-chip oscillator clock.
- Note 2: The CPU clock can be switched from the high-speed on-chip oscillator clock to the high-speed system clock or the subsystem clock. In the case of X1 clock, the switch must be made after checking the oscillation stability time by the status register of the oscillation stability time counter (OSTC); in the case of XT1 clock, the switch must be made after checking the oscillation stability time by the timer function, etc.
- Note 3: When LVD is OFF, the external reset of RESETB pin must be used. For details, please refer to "Chapter 21 Voltage Detection Circuit".
- Notice: When the power supply voltage rises, the power supply voltage must be maintained by external reset before it reaches the working voltage range shown in the AC characteristics of the data sheet; When the supply voltage drops, it must be reset through deep sleep mode transfer, voltage detection circuitry, or external reset before the supply voltage falls below the operating voltage range. When restarting operation, you must confirm that the supply voltage has returned to the operating voltage range.

Remark: V<sub>POR</sub>: POR power supply rise detection voltage; V<sub>PDR</sub>: POR power supply fall detection voltage

www.mcu.com.cn 570 / 624 Rev.1.0.3

Figure 20-2: Timing of internal reset signal generation for power-on reset circuit and voltage detection circuit (2/3)

(2) LVD interrupt & reset mode (option byte 000C1: LVIMDS1, LVIMDS0=1, 0)

- Note 1: The internal reset processing time includes the oscillation accuracy stabilization wait time of the high-speed on-chip oscillator clock.
- Note 2: The CPU clock can be switched from the high-speed on-chip oscillator clock to the high-speed system clock or the subsystem clock. In the case of X1 clock, the switch must be made after checking the oscillation stability time by the status register of the oscillation stability time counter (OSTC); in the case of XT1 clock, the switch must be made after checking the oscillation stability time by the timer function, etc.
- Note 3: After generating the interrupt request signal (INTLVI), the LVIV bit and the LVIMD bit of the voltage detection level register (LVIS) are automatically set to "1". Therefore, considering the possibility that the power supply voltage may return to the high voltage detection voltage (VLVDH) or higher without falling below the low voltage detection voltage (VLVDL), follow the steps in "Fig. 21-5 Setting Procedure for Confirmation/Reset of Operating Voltage" and "Fig. 21-6 Setting Procedure for Interrupt and Reset" after generating INTLVI. "Figure 21-6 Initial Setting Procedure for Interrupt & Reset Mode" after generating INTLVI.
- Note 4: The time until normal operation begins includes the "Voltage Stabilization Wait + POR Reset Processing Time" after VPOR (1.51V (typical)) is reached as well as the "LVD Reset Processing Time" after the LVD detection level (VLVD) is reached.

Remark: V<sub>LVDH</sub>, V<sub>LVDL</sub>: LVD detection voltage

V<sub>POR</sub>: POR supply voltage rising detection voltage

V<sub>PDR</sub>: POR power supply fall detection voltage

www.mcu.com.cn 571 / 624 Rev.1.0.3

Figure 20-2: Timing of internal reset signal generation for power-on reset circuit and voltage detection circuit (3/3)

- Note 1: The internal reset processing time includes the oscillation accuracy stabilization wait time of the high-speed on-chip oscillator clock.
- Note 2: The CPU clock can be switched from the high-speed on-chip oscillator clock to the high-speed system clock or the subsystem clock. In the case of X1 clock, the switch must be made after checking the oscillation stability time by the status register of the oscillation stability time counter (OSTC); in the case of XT1 clock, the switch must be made after checking the oscillation stability time by the timer function, etc.
- Note 3: The time until normal operation starts includes the following LVD reset processing time after the LVD detection level (V<sub>LVD</sub>) is reached as well as the voltage stabilization wait + POR reset processing time after the VPOR (1.51 V, typ.) is reached.
- Note 4: When the power supply voltage is below the lower limit for operation and the power supply voltage is then restored after an internal reset is generated only by the voltage detection circuit (LVD), the following LVD reset processing time is required after the LVD detection level (VLVD) is reached.

#### Remark:

1.  $V_{LVDH}$ ,  $V_{LVDL}$ : LVD detection voltage  $V_{POR}$ : POR supply voltage rise detection voltage

V<sub>PDR</sub>: POR supply voltage drop detection voltage

2. When the LVD interrupt mode is selected (option byte 000C1H: LVIMD1 = 0, LVIMD0 = 1), the time until normal operation starts after power is turned on is the same as the time specified in Note 3 of Figure 20-2 (3/3).

www.mcu.com.cn 572 / 624 Rev.1.0.3

## **Chapter 21 Voltage Detection Circuit**

## 21.1 Function of voltage detection circuit

The voltage detection circuit sets the operating mode and detection voltage ( $V_{LVDH}$ ,  $V_{LVDL}$ ,  $V_{LVD}$ ) by option byte (000C1H). The voltage detection circuit (LVD) has the following functions.

- (1) The internal reset or internal interrupt signal is generated by comparing the supply voltage (V<sub>DD</sub>) with the detection voltage (V<sub>LVDH</sub>, V<sub>LVDL</sub>, V<sub>LVD</sub>).
- (2) The detection voltage of the supply voltage (V<sub>LVDH</sub>, V<sub>LVDL</sub>) can be selected from 12 detection levels by means of option bytes (see "Chapter 24 Option Bytes").
- (3) It can also operate in deep sleep mode.
- (4) When the supply voltage rises, the reset state must be maintained by the voltage detection circuit or external reset before the supply voltage reaches the operating voltage range shown in the AC characteristics of the datasheet; when the supply voltage falls, the reset state must be set by the deep sleep mode transfer, voltage detection circuit or external reset before the supply voltage falls below the operating voltage range. The operating voltage range depends on the setting of the user option byte (000C2H/010C2H).

The voltage detection circuit has the following 3 operation mode settings.

- (1) Interrupt & reset mode (LVIMDS1, LVIMDS0=1, 0 of option byte)
  Two detection voltages (V<sub>LVDH</sub>, V<sub>LVDL</sub>) are selected by the option byte 000C1H. The high voltage detection level (V<sub>LVDH</sub>) is used to release the reset or generate an interrupt, and the low voltage detection level (V<sub>LVDL</sub>) is used to generate a reset.
- (2) Reset mode (LVIMDS1, LVIMDS0=1, 1 for option byte)

  A detection voltage (V<sub>LVD</sub>) selected by option byte 000C1H is used to generate or release the reset.
- (3) Interrupt mode (option byte of LVIMDS1, LVIMDS0=0, 1)
  A detection voltage (V<sub>LVD</sub>) selected by option byte 000C1H is used to generate an interrupt or to release the reset. In each mode, the following interrupt signals and internal reset signals are generated.

Table 21-1: Modes of voltage detection circuits

| Interrupt & reset mode (LVIMDS1, LVIMDS0=1, 0) | Reset mode<br>(LVIMDS1, LVIMDS0=1, 1) | Interrupt mode<br>(LVIMDS1, LVIMDS0=0, 1)  |
|--|---------------------------------------|--|
| when vod < vlydh is delected, when vod         |                                       | After a reset occurs, an internal reset state of LVD continues until $V_{DD} \geqslant V_{LVD}$ . When $V_{DD} \geqslant V_{LVD}$ is detected, an internal reset of LVD is released. After the internal reset of LVD is released, if $V_{DD} < V_{LVD}$ or $V_{DD} \geqslant V_{LVD}$ is detected, then an interrupt request signal (INTLVI) is generated. |

When the voltage detection circuit is in operation, it is possible to check whether the power supply voltage is greater than or less than the detection voltage by reading the voltage detection flag (LVIF: bit 0 of the voltage detection register (LVIM)).

If a reset occurs, bit 0 (LVIRF) of the reset control flag register (RESF) is set to "1". For details of the RESF register, please refer to "Chapter 19 Reset Function".

## 21.2 Structure of voltage detection circuit

The block diagram of the voltage detection circuit is shown in Figure 21-2.

Figure 21-2: Block diagram of voltage detection circuit

## 21.3 Registers for controlling voltage detection circuit

The voltage detection circuit is controlled by the following registers.

- (1) Voltage detection register (LVIM)
- (2) Voltage detection level register (LVIS)

www.mcu.com.cn 574 / 624 Rev.1.0.3

### 21.3.1 Voltage detection register (LVIM)

This register is set to enable or disable overwriting of the voltage detection level register (LVIS), and to confirm the masking status of the LVD output. The LVIM register is set by an 8-bit memory manipulation instruction. After a reset signal is generated, the value of this register becomes "00H".

Table 21-3: Format of voltage detection register (LVIM)

| Address | s: 40020441H            | After reset | t: 00H <sup>Note1</sup> | R/W <sup>Note2</sup> |   |   |         |      |
|---------|-------------------------|-------------|-------------------------|----------------------|---|---|---------|------|
| Symbol  | 7                       | 6           | 5                       | 4                    | 3 | 2 | 1       | 0    |
| LVIM    | LVISEN <sup>Note3</sup> |             |                         |                      |   |   | LVIOMSK | LVIF |

| LVISEN <sup>Note3</sup> Enable/disable setting of voltage detection level register (LVIS) |   |
|---|---|
| 0   | Disable rewriting LVIS register (LVIOMSK=0 (LVD output mask is invalid)). |
| 1   | Enable rewriting LVIS register (LVIOMSK=1 (LVD output mask valid)).       |

| LVIOMSK | Mask status flag for LVD output     |  |  |
|---------|-------------------------------------|--|--|
| 0       | LVD output masking is invalid.      |  |  |
| 1       | LVD output masking is valid Note 4. |  |  |

| LVIF | Voltage detection flag   |
|------|--|
| 0    | Supply voltage $(V_{DD}) \ge$ detection voltage $(V_{LVD})$ or LVD is OFF. |
| 1    | Supply voltage (V <sub>DD</sub> ) < detection voltage (V) <sub>LVD</sub>   |

- Note 1: The reset value varies depending on the reset source. When the LVD is reset, the value of the LVIM register is not reset and the original value is maintained; During other resets, clear LVISEN to "0".
- Note 2: Bit0 and bit1 of the LVIM register are read-only bits.
- Note 3: It can only be set when the interrupt & reset mode is selected (IvIMDS1 bits and LVIMDS0 bits of the option bytes are "1" and "0" respectively), the initial value cannot be changed in other modes.
- Note 4: Only when the interrupt & reset mode is selected (the LVIMDS1 bit and LVIMDS0 bits of the option byte are "1" and "0" respectively). The LVIOMSK bit automatically changes to "1" during the following periods, masking the reset or interrupt generated by LVD.
  - ① When LVISEN=1.
  - (2) Waiting time from the occurrence of LVD interrupt to the stabilization of LVD detection voltage
  - Waiting time from changing the value of the LVILV bit (bit0 of the LVIS register) until the LVD detection voltage stabilizes.

www.mcu.com.cn 575 / 624 Rev.1.0.3

## 21.3.2 Voltage detection level register (LVIS)

This is a register that sets the voltage sense level. The LVIS register is set by an 8-bit memory manipulation instruction. After generating a reset signal, the value of this register changes to "00H/01H/81H" Note1.

Table 21-4: Format of voltage detection level register (LVIS)

| Address | s: 40020442H           | After reset: 001 | -d/01H/81H <sup>Note1</sup> | R/W |   |   |   |       |
|---------|------------------------|------------------|-----------------------------|-----|---|---|---|-------|
| Symbol  | 7                      | 6                | 5                           | 4   | 3 | 2 | 1 | 0     |
| LVIS    | LVIMD <sup>Note2</sup> |                  |                             |     |   |   | 0 | LVILV |

| LVIMD <sup>Note2</sup> | Operation mode of voltage detection |
|------------------------|-------------------------------------|
| 0                      | Interrupt mode                      |
| 1                      | Reset mode                          |

| LVILV <sup>Note2</sup> | LVD detection level  |
|------------------------|--|
| 0                      | High voltage detection level (V <sub>LVDH</sub> )                    |
| 1                      | Low voltage detection level (V <sub>LVDL</sub> or V <sub>LVD</sub> ) |

- Note 1: The reset value varies depending on the setting of the reset source and option bytes. When an LVD reset occurs, this register is not cleared to "00H". When a reset other than LVD occurs, the values of this register are as follows:
  - 1 LVIMDS1, LVIMDS0 of Option bytes =1, 0: 00H
  - 2 LVIMDS1, LVIMDS0 of Option bytes =1, 1: 81H
  - (3) LVIMDS1, LVIMDS0 of Option bytes =0, 1: 01H
- Note 2: Write "0" only if interrupt & reset mode is selected (LVIMDS1 bit and LVIMDS0 bits for option bytes are "1" and "0" respectively). In other cases, it cannot be set. In interrupt & reset mode, value substitution is performed automatically by generating a reset or interrupt.
- Notice: To rewrite the LVIS registers, it must be done in accordance with the steps in Figure 21-5 and Figure 21-6.
- Remark: Option byte 000C1H selects the mode of operation of the LVD and the detection voltage ( $V_{LVDH}$ ,  $V_{LVD}$ ) for each mode. The format of the user option byte (000C1H/010C1H) is shown in Table 21-4. For details of the option byte, refer to "Chapter 24 Option Bytes".

www.mcu.com.cn 576 / 624 Rev.1.0.3

#### Notice:

- 1. Write "1" to bit4 in interrupt mode.
- 2. When the power supply voltage rises, the reset state must be maintained through the voltage detection circuit or external reset before the power supply voltage reaches the working voltage range shown in the AC characteristics of the data sheet; When the supply voltage drops, it must be reset by transferring in deep sleep mode, voltage detection circuitry, or external reset before the supply voltage falls below the operating voltage range.

#### Remark:

- 3. x: Ignore.
- 4. The detection voltage is a TYP value. For details, please refer to the LVD circuit characteristics in the data sheet.

www.mcu.com.cn 579 / 624 Rev.1.0.3

### 21.4 Operation of voltage detection circuit

#### 21.4.1 When used as reset mode

The operation mode (reset mode (LVIMDS1, LVIMDS0=1, 1)) and the detection voltage ( $V_{LVD}$ ) are set via the option byte 000C1H. If the reset mode is set, operation starts with the following initial settings.

- (1) Set bit 7 (LVISEN) of the voltage detection register (LVIM) to "0" (disable rewriting the voltage detection level register (LVIS))
- (2) Set the initial value of the voltage detection level register (LVIS) to "81H". Set bit7(LVIMD) to "1" (reset mode). Set bit0 (LVILV) to "1"(voltage detection level: V<sub>LVD</sub>).

#### Operation of LVD reset mode:

When the power is turned on, the reset mode (LVIMDS1, LVIMDS0=1, 1 of the option byte) keeps the internal reset state of LVD until the supply voltage ( $V_{DD}$ ) exceeds the voltage detection level ( $V_{LVD}$ ). If the supply voltage ( $V_{DD}$ ) exceeds the voltage detection level ( $V_{LVD}$ ), the internal reset is released. When the operating voltage falls, an internal reset of LVD is generated if the supply voltage ( $V_{DD}$ ) is below the voltage detection level ( $V_{LVD}$ )

The timing of the internal reset signal generation for LVD reset mode is shown in Figure 21-2. Figure 21-2: Timing of internal reset signal generation (LVIMDS1, LVIMDS0=1, 1 for option byte)

Remark: V<sub>POR</sub>: POR power supply rise detection voltage; V<sub>PDR</sub>: POR power supply fall detection voltage

www.mcu.com.cn 580 / 624 Rev.1.0.3

### 21.4.2 When used as interrupt mode

The operation mode (interrupt mode (LVIMDS1, LVIMDS0=0, 1)) and the detection voltage ( $V_{LVD}$ ) are set via the option byte 000C1H. If the interrupt mode is set, operation starts with the following initial settings.

- (1) Set bit 7 (LVISEN) of the voltage detection register (LVIM) to "0" (disables rewriting the voltage detection level register (LVIS)).
- (2) Set the initial value of the voltage detection level register (LVIS) to "01H". Set bit7 (LVIMD) to "0" (interrupt mode). Set bit0(LVILV) to "1" (voltage detection level: V<sub>LVD</sub>).

#### Operation of LVD interrupt mode:

After generating a reset, the interrupt mode (LVIMDS1, LVIMDS0 of the option byte =0, 1) maintains the internal reset state of the LVD until the supply voltage ( $V_{DD}$ ) exceeds the voltage detection level ( $V_{LVD}$ ). If the supply voltage ( $V_{DD}$ ) exceeds the voltage detection level ( $V_{LVD}$ ), the internal reset of the LVD is released.

If the supply voltage  $(V_{DD})$  exceeds the voltage detection level  $(V_{LVD})$  after the internal reset of the LVD is released, an interrupt request signal (INTLVI) of the LVD is generated. When the operating voltage drops, it must be set to the reset state by deep sleep mode transfer or external reset before the operating voltage falls below the operating voltage range shown in the AC characteristics of the datasheet. When restarting operation, it must be verified that the supply voltage has returned to the operating voltage range.

The timing of the interrupt request signal generation for LVD interrupt mode is shown in Figure 21-3.

www.mcu.com.cn 581 / 624 Rev.1.0.3

Figure 21-3: Timing of interrupt signal generation (LVIMDS1, LVIMDS0 of option byte =0, 1)

Note 1: After generating a reset signal, the LVIMK flag changes to "1".

Note 2: When the operating voltage drops, it must be reset by deep sleep mode transfer or external reset before the operating voltage falls below the operating voltage range shown in the AC characteristics of the data sheet. When restarting operation, it must be verified that the supply voltage returns to the operating voltage range.

Remark: VPOR: POR power supply rise detection voltage; VPDR: POR power supply fall detection voltage

www.mcu.com.cn 582 / 624 Rev.1.0.3

### 21.4.3 When used as interrupt & reset mode

The operation mode (interrupt & reset mode (LVIMDS1, LVIMDS0=1, 0)) and the detection voltage ( $V_{LVDH}$ ,  $V_{LVDL}$ ) are set via the option byte 000C1H. If the interrupt & reset mode is set, the operation starts with the following initial settings.

- (1) Set bit 7 (LVISEN) of the voltage detection register (LVIM) to "0" (disables rewriting the voltage detection level register (LVIS)).
- (2) Set the initial value of the voltage detection level register (LVIS) to "00H". Set bit7 (LVIMD) to "0" (interrupt mode). Set bit0(LVILV) to "0" (high voltage detection level: V<sub>LVDH</sub>).

#### Operation of LVD interrupt & reset mode:

When power is turned on, the interrupt & reset mode (LVIMDS1, LVIMDS0=1, 0 of the option byte) maintains the internal reset state of the LVD until the power supply voltage ( $V_{DD}$ ) exceeds the high voltage detection level ( $V_{LVDH}$ ). If the supply voltage ( $V_{DD}$ ) exceeds the high voltage detection level ( $V_{LVDH}$ ), the internal reset is released.

When the operating voltage drops, if the supply voltage  $(V_{DD})$  is below the high voltage detection level  $(V_{LVDH})$ , an interrupt request signal (INTLVI) is generated for the LVD and any stacking process can be performed. After that, if the supply voltage  $(V_{DD})$  is below the low voltage detection level  $(V_{LVDL})$ , an internal reset of the LVD is generated. However, after INTLVI occurs, no interrupt request signal is generated even if the supply voltage  $(V_{DD})$  returns to the high voltage detection voltage  $(V_{LVDH})$  or higher without falling below the low voltage detection voltage  $(V_{LVDL})$ .

When using LVD interrupt & reset mode, you must follow "Figure 21-5: Setting procedure for confirmation /reset of operating voltage" and "Figure 21-6: Initial setting procedure for interrupt & reset mode".

The timing of the internal reset signal and interrupt signal generation in LVD interrupt & reset mode is shown in Figure 21-4.

www.mcu.com.cn 583 / 624 Rev.1.0.3

Figure 21-4: Reset & interrupt signal generation timing (LVIMDS1, LVIMDS0=1, 0) (1/2)

Note 1: After the reset signal is generated, the LVIMK flag becomes "1".

Note 2: When using the interrupt & reset mode, you must follow "Figure 21-5: Setting procedure for

confirmation /reset of operating voltage" after an interrupt occurs.

Note 3: When using the interrupt&reset mode, you must follow the steps in "Figure 21-6: Initial setting procedure for interrupt & reset mode" after the reset is released.

Figure 21-5: Setting procedure for confirmation/reset of operating voltage

If the interrupt & reset mode is set (LVIMDS1, LVIMDS0=1, 0), it will take 400us or 5  $F_{IL}$  clocks for the voltage detection to stabilize after the LVD reset (LVIRF=1) is released. The LVIMD bit must be cleared to "0" for initialization after waiting for the voltage detection to stabilize. The LVISEN bit must be set to "1" during the count of the voltage detection stabilization time and when rewriting the LVIMD bit to block the generation of resets or interrupts generated by LVD.

The initial setting procedure for interrupt & reset mode is shown in Figure 21-6.

Figure 21-6: Initial setting procedure for interrupt & reset mode

Remark: F<sub>IL</sub>: Low-speed on-chip oscillator clock frequency

www.mcu.com.cn 589 / 624 Rev.1.0.3

### 21.5 Cautions for voltage detection circuits

(1) Voltage fluctuation when power is supplied
In a system where the supply voltage (V<sub>DD</sub>) fluctuates for a certain period in the vicinity of the LVD
detection voltage, the system may be repeatedly reset and released from the reset status. In this
case, the time from release of reset to the start of the operation of the microcontroller can be
arbitrarily set by taking the following action. After releasing the reset signal, wait for the supply
voltage fluctuation period of each system by means of a software counter that uses a timer, and then
initialize the ports.

Figure 21-7: Example of software processing when the supply voltage fluctuation near the LVD detection voltage does not exceed 50ms

Note: If the reset occurs again during this period, it is not switched to initialization processing 2.

www.mcu.com.cn 590 / 624 Rev.1.0.3

(2) Delay from generation of LVD reset source to generation or release of LVD reset

A delay occurs from the time the supply voltage  $(V_{DD}) < LVD$  detection voltage  $(V_{LVD})$  is met to the time the LVD reset is generated. Similarly, a delay occurs from the time the LVD detection voltage  $(V_{LVD}) \le$  the supply voltage  $(V_{DD})$  to the time the LVD reset is released (see Figure 21-8).

Figure 21-8: Delay from generation of LVD reset source to generation or release of LVD reset

Remark: ①: Detection delay (300us(MAX.))

- (1) When the power is turned on with LVD set to OFF When LVD is set to OFF, an external reset must be performed using the RESETB pin. When performing an external reset, the RESETB pin must be input low for at least 10us. If an external reset is performed while the supply voltage is rising, the power must be turned on after a low level is input to the RESETB pin, and must be held low for at least 10us within the operating voltage range shown in the AC characteristics of the datasheet, followed by a high level.
- (2) When LVD is set to OFF in LVD interrupt mode and the operating voltage drops If the operating voltage drops when LVD is set to OFF and LVD interrupt mode is set, it must be reset by deep sleep mode transfer or external reset before the operating voltage falls below the operating voltage range shown in the AC characteristics of the data sheet. When restarting operation, it is necessary to verify that the supply voltage is restored in the operating voltage range.

www.mcu.com.cn 591 / 624 Rev.1.0.3

# **Chapter 22 Safety Function**

### 22.1 Summary of safety functions

In order to comply with IEC60730 and EC61508 safety standards, the CMS32L032 has the following built-in safety features.

The purpose of this function is to safely stop the operation when a fault is detected through the self-diagnosis of the microcontroller.

(1) Flash CRC function (high-speed CRC, general-purpose CRC)

The data error of flash memory is detected by CRC operation. The following two CRCs can be used depending on the application and usage conditions.

- ① "High-speed CRC"...During the initialization program, it is possible to stop the CPU and check the entire code flash area at high speed.
- ② "General-purpose CRC"...can be used for multi-purpose checks during CPU operation, not limited to the code flash area.
- (2) SFR guard function

This prevents SFRs from being rewritten when the CPU freezes.

- (3) Frequency detection function
  - Self-testing of CPU/peripheral hardware clock frequency using a general-purpose timer unit.
- (4) A/D test function
  - A/D converter self-test by A/D conversion of positive (+) reference voltage, negative (-) reference voltage, analog input channel (ANI), temperature sensor output and internal reference voltage output of A/D converter.
- (5) Digital output signal level detection function for input/output ports
  When the input/output port is in output mode, the output level of the pin can be read.

### 22.2 Registers used for safety functions

The following registers are used for each function of the security function.

| Register Name                                     | Function   |
|---|--|
| Flash CRC control register (CRC0CTL)              | Flash CRC operation function   |
| Flash CRC operation result register (PGCRCL)      | (High-speed CRC)   |
| CRC input register (CRCIN)                        | CRC calculation function   |
| CRC data register (CRCD)                          | (General CRC)  |
| Special SFR protection control register (SFRGD)   | SFR guard function   |
| Timer input select register 0 (TIS0)              | Frequency detection function   |
| Analog input channel specification register (ADS) | A/D test function  |
| Port mode selection register (PMS)                | Digital output signal level detection function for input/output pins |

The contents of each register are described in "22.3 Operation of safety function".

### 22.3 Operation of safety functions

### 22.3.1 Flash CRC operation function (high-speed CRC)

The IEC60730 standard requires verification of the data in the flash memory and recommends CRC as a means of verification. This high-speed CRC can check the entire code flash area in the initial setup (initialization) procedure.

High-speed CRC stops the CPU and reads 32 bits of data from the flash memory with one clock for operation. Therefore, it is characterized by a short time to complete the verification (e.g., 64KB flash: 512us@32MHz).

The CRC generation polynomial used complies with " $X^{16}+X^{12}+X^5+1$ " of CRC-16-CCITT. MSB of bit31 $\rightarrow$ bit0 is operated first.

Remark: The operation result is differentbecause the general CRC operates in LSB first order.

#### 1.1.1.1 Flash memory CRC control register (CRC0CTL)

This register is used to control the operation of the high-speed CRC ALU, as well as to specify the operation range. The CRC0CTL register can be set by an 8-bit memory manipulation instruction. Reset signal generation clears this register to 00H.

Table 22-1: Format of flash memory CRC control register (CRC0CTL)

Address: 40021810H After reset: R/W 00H

| Symbol  | 7      | 6        | 5 | 4 | 3 | 2    | 1    | 0    |
|---------|--------|----------|---|---|---|------|------|------|
| CRC0CTL | CRC0EN | CRCCHK60 | 0 | 0 | 0 | FEA2 | FEA1 | FEA0 |

| CRC0EN | Control of CRC ALU operation                           |  |  |  |
|--------|--|--|--|--|
| 0      | 0 Operation stopped                                    |  |  |  |
| 1      | Operation is started by executing the WFE instruction. |  |  |  |

| CRCCHK60 | FEA2 | FEA1 | FEA0 | High-speed CRC operation range |
|----------|------|------|------|--------------------------------|
| 0        | 0    | 0    | 0    | 00000H ~ 1FFBH(8K-4byte)       |
| 0        | 0    | 0    | 1    | 00000H ~ 3FFBH(16K-4byte)      |
| 0        | 0    | 1    | 0    | 00000H ~ 5FFBH(24K-4byte)      |
| 0        | 0    | 1    | 1    | 00000H ~ 7FFBH(32K-4byte)      |
| 0        | 1    | 0    | 0    | 00000H ~ 9FFBH(40K-4byte)      |
| 0        | 1    | 0    | 1    | 00000H ~ BFFBH(48K-4byte)      |
| 0        | 1    | 1    | 0    | 00000H ~ DFFBH(56K-4byte)      |
| 0        | 1    | 1    | 1    | 00000H ~ FFFBH(64K-4byte)      |
| 1        | 0    | 0    | 0    | 00000H ~ EFFFBH(60K-4byte)     |

#### Notice:

- Bit3~5 must be set to 0.
- 2. Input the expected CRC operation result value to be used for comparison in the lowest 4 bytes of the flash memory. Note that the operation range will thereby be reduced by 4 bytes.

### 1.1.1.2 Flash memory CRC operation result register (PGCRCL)

This register is used to store the high-speed CRC operation results.

The PGCRCL register can be set by a 16-bit memory manipulation instruction.

Reset signal generation clears this register to 0000H.

Table 22-2: Format of memory CRC operation result register (PGCRCL)

| Address: | : 0x40021812 |         | After reset: 0000H |         |         | R/W     |        |        |
|----------|--------------|---------|--------------------|---------|---------|---------|--------|--------|
| Symbol   | 15           | 14      | 13                 | 12      | 11      | 10      | 9      | 8      |

| PGCRC15~0   | High-speed CRC operation results            |
|-------------|---|
| 0000H~FFFFH | Store the high-speed CRC operation results. |

Notice: The PGCRCL register can only be written if CRC0EN (bit 7 of the CRC0CTL register) = 1.

www.mcu.com.cn 594 / 624 Rev.1.0.3

The flowchart of the flash memory CRC operation function (high-speed CRC) is shown in Figure 22-1. <Operation flow>

Figure 22-1: Flow chart of flash CRC operation function (high-speed CRC)

#### Notice:

- 1. The CRC operation is executed only on the code flash.
- 2. Store the expected CRC operation value in the area below the operation range in the code flash.

### 22.3.2 CRC operation function (general-purpose CRC)

In order to guarantee safety during operation, the IEC61508 standard mandates the checking of data even while the CPU is operating.

The general CRC operation can be executed as a peripheral function while the CPU is operating. The general CRC can be used for checking various data in addition to the code flash memory area. The data to be checked can be specified by using software (a user-created program).

The general CRC operation can be executed in the main system clock operation mode as well as the subsystem clock operation mode.

The CRC generator polynomial used is "X<sup>16</sup>+X<sup>12</sup>+X<sup>5</sup>+1" of CRC-16-CCITT. The data to be input is inverted in bit order and then calculated to allow for LSB-first communication. For example, if the data 12345678H is sent from the LSB, values are written to the CRCIN register in the order of 78H, 56H, 34H, and 12H, enabling a value of 08F6H to be obtained from the CRCD register. This is the result obtained by executing a CRC operation on the bit rows shown below, which consist of the data 12345678H inverted in bit order.

Remark: Because the debugger rewrites the software break setting line to a break instruction during program execution, the CRC operation result differs if a software break is set in the CRC operation target area.

www.mcu.com.cn 596 / 624 Rev.1.0.3

### 1.1.1.3 CRC input register (CRCIN)

CRCIN register is an 8-bit register that is used to set the CRC operation data of general-purpose CRC. The possible setting range is 00H to FFH.

The CRCIN register can be set by an 8-bit memory manipulation instruction. Reset signal generation clears this register to 00H.

| Table 22-3: Format of | f CRC input | t register | (CRCIN) |
|-----------------------|-------------|------------|---------|
|-----------------------|-------------|------------|---------|

| Address: | 400433ACH | After reset:<br>00H | R/W |   |   |   |   |   |

| CRCIN    |           |                     |     |   |   |   |   |   |
| _        |           |                     |     |   |   |   |   |   |

| bit7~0  | Function   |
|---------|------------|
| 00H~FFH | Data input |

www.mcu.com.cn 597 / 624 Rev.1.0.3

### 1.1.1.4 CRC data register (CRCD)

This register is used to store the CRC operation result of the general-purpose CRC. The setting range is 0000H to FFFFH.

After 1 clock of CPU/peripheral hardware clock (F<sub>CLK</sub>) has elapsed from the time CRCIN register is written, the CRC operation result is stored to the CRCD register.

The CRCD register can be set by a 16-bit memory manipulation instruction.

Reset signal generation clears this register to 0000H.

Table 22-4: Format of CRC data register (CRCD)

| Address: 400432FAH |    | After reset: 0000H |    | R/W |    |    |   |   |   |   |   |   |   |   |   |   |
|--------------------|----|--------------------|----|-----|----|----|---|---|---|---|---|---|---|---|---|---|
| Symbol             | 15 | 14                 | 13 | 12  | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| CRCD               |    |                    |    |     |    |    |   |   |   |   |   |   |   |   |   |   |

The flowchart of the CRC operation function is shown in Figure 22-2.

#### <Operation flow>

Figure 22-2: CRC operation function (general-purpose CRC) Start Store the start and end addresses in a Specify the start and end addresses general-purpose register. Write CRCD register to 0000H Initialize CRCD register Read data Read 8-bit data of corresponding address Store data to CRCIN register Execute CRC calculation for 8-bit data Address+1 Last address? Yes No 1 clock wait (F<sub>CLK</sub>) Get CRC result Read CRCD register Compare the value with the stored expected value and make End sure that the values match.

Notice:

- 1. To read the write value of the CRCD register, the CRCD register must be read before the CRCIN register is written.
- 2. If a write operation to the CRCD register competes with the saving of an operation result, the write operation is ignored.

www.mcu.com.cn 599 / 624 Rev.1.0.3

### 22.3.3 SFR guard function

In order to ensure safety during operation, the IEC61508 standard requires that even if the CPU is out of control, it is necessary to protect important SFR from being rewritten. The SFR protection function is used to protect data from the control registers of the comparator function, port function, interrupt function, clock control function, and voltage detection circuitry.

If the SFR protection function is set, the write operation of the protected SFR is invalid, but it can be read normally.

#### 1.1.1.5 SFR guard control register (SFRGD)

This register controls whether the SFR guard function is valid.

The SFR guard function uses GCOMP bits, GPORT bits, GINT bits, and GCSC bits.

The SFRGD register is set by an 8-bit memory manipulation instruction.

After a reset signal is generated, the value of this register becomes "00H".

Table 22-5: Format of SFR guard control register (SFRGD)

| Address: 40040478H |   | After reset:<br>00H | R/W |   |   |       |      |      |
|--------------------|---|---------------------|-----|---|---|-------|------|------|
| Symbol             | 7 | 6                   | 5   | 4 | 3 | 2     | 1    | 0    |

Remark: Pxx (port register) is not protected.

### 22.3.4 Frequency detection function

The IEC60730 standard mandates checking that the oscillation frequency is correct.

By using the CPU/peripheral hardware clock frequency (F<sub>CLK</sub>) and measuring the pulse width of the input signal to channel 1 of the Timer40, whether the proportional relationship between the two clock frequencies is correct can be determined.

Note that, however, if one or both clock operations are completely stopped, the proportional relationship between the clocks cannot be determined.

<Clocks to be compared>

- (1) CPU/peripheral hardware clock frequency (F<sub>CLK</sub>):
  - 1 High-speed on-chip oscillator clock (FiH)
  - ② High-speed system clock (F<sub>MX</sub>)
- (2) Input to Chanel 1 of the Timer40:
  - ① Timer input to channel 1 (TI01)
  - 2 Low-speed on-chip oscillator clock (F<sub>IL</sub>: 15KHz(typ.))
  - 3 Subsystem clock (F<sub>SUB</sub>)<sup>Note</sup>

High-speed on-chip oscillator clock (FIH)  $F_{CLK}$ High-speed system clock (F<sub>MX</sub>) 1 TI01 (( Channel 1 of general-2 Selector purpose timer unit 0 (Timer40) Subsystem clock (F<sub>SUB</sub>) Low-speed on-chip  $F_{\mathsf{IL}}$ Watchdog timer oscillator clock (WDT) (15 Khz (TYP.))

Figure 22-3: Structure of frequency detection function

If the measurement result of the input pulse interval is an abnormal value, it can be judged as "clock frequency abnormality". For the measurement method of the input pulse interval, refer to "5.8.4 Operation as input pulse interval measurement".

Note: Only products with built-in subsystem clocks can be selected.

### 1.1.1.6 Timer input select register0(TIS0)

Refer to Section 5.3.8 for register descriptions.

#### 22.3.5 A/D test function

The IEC60730 standard requires testing the A/D converter. This A/D test function is performed on the positive (+) reference voltage, negative (–) reference voltage, analog input channel (ANI), output voltage of the temperature sensor, and internal reference voltage for A/D conversion to confirm that the A/D converter is running normally.

The analog multiplexer can be confirmed by following these steps:

- ① Select the ANIx pin for A/D conversion using the ADS register.
- 2 Perform A/D conversion for the ANIx pin (conversion result 1-1).
- The positive (+) reference voltage of the A/D converter is selected for A/D conversion via the ADS register.
- Perform A/D conversion of the positive (+) reference voltage of the A/D converter (conversion result 2-1)
- (5) Select the ANIx pin for A/D conversion using the ADS register.
- (6) Perform A/D conversion for the ANIx pin (conversion result 1-2).
- (7) Check that the conversion results 1-1 and 1-2 are equal.
- Check that the A/D conversion result 2-1 is all zero
   Using the procedure above can confirm that the analog multiplexer is selected and all wiring is connected.

#### Notice:

- 1. If the analog input voltage is variable during A/D conversion in steps ①-®above, use another method to check the analog multiplexer.
- 2. The conversion results might contain an error. Consider an appropriate level of error when comparing the conversion results.

#### 1.1.1.7 Analog input channel specification register (ADS)

This register specifies the input channel of the analog voltage to be A/D converted.

ANIxx, temperature sensor output, internal reference voltage (1.45V) or positive (+) reference voltage can be measured via the A/D test function.

Refer to 11.2.7 for register descriptions.

www.mcu.com.cn 602 / 624 Rev.1.0.3

# 22.3.6 Digital output signal level detection function for input/output pins

The IEC60730 standard requires confirmation that the I/O function is normal.

Input/output pin digital output signal level detection function reads the digital output level of a pin when the pin is in output mode.

#### 1.1.1.8 Port mode select register (PMS)

This register selects whether to read the value of the port's output latch or the output level of the pin when the pin is in output mode (PMmn bit of the Port Mode Register (PMm) is "0").

The PMS register is set by an 8-bit memory manipulation instruction.

After a reset signal is generated, the value of this register changes to "00H".

Table 22-6: Format of port mode select register (PMS)

| Address | s: 4004087BH | After reset:<br>00H | R/W |   | J | , |   |      |
|---------|--------------|---------------------|-----|---|---|---|---|------|
| Symbol  | 7            | 6                   | 5   | 4 | 3 | 2 | 1 | 0    |
| PMS     | 0            | 0                   | 0   | 0 | 0 | 0 | 0 | PMS0 |

|   | PMS0 | Selection of reading data when the pin is in output mode |
|---|------|--|
| Ī | 0    | Reads the value of the Pmn register.                     |
| Ī | 1    | Read the digital output level of the pin.                |

#### Remark:

- 1. If the digital output level of the pin is read, the read value is "0" for the pin that has been changed to a high impedance state by using the pulse output forced truncation function of Timer M.
- 2. m=0~3 n=0~7

www.mcu.com.cn 603 / 624 Rev.1.0.3

### 22.3.7 Product unique identification register

The unique identification of the product is perfect for:

- (1) Used as a serial number (e.g. USB character serial number or other terminal applications).
- (2) Used as a password, this unique identifier is used in conjunction with a software encryption and decryption algorithm when writing flash memory to improve the security of the code in the flash memory.
- (3) Used to activate a bootstrap process with a safety mechanism

  The reference number provided by the 128-bit product unique identifier is unique to any microcontroller in any case. Under any circumstances, the user cannot modify this identity.

# **Chapter 23 Temperature sensor**

### 23.1 Function of temperature sensor

The on-chip temperature sensor measures and monitors the core temperature of the product, thus ensuring reliable operation of the product. The voltage output by the temperature sensor is proportional to the core temperature, and there is a linear relationship between the voltage and temperature. Its output voltage is supplied to the ADC for conversion. Figure 23-1 shows a block diagram of a temperature sensor.

 TSN25
 TSN25[11:0]
 R

It is a read-only register for recording the calibration data1 of the temperature sensor, which is automatically loaded when power is turned on or reset is initiated, and each chip has its own calibration data.

www.mcu.com.cn 605 / 624 Rev.1.0.3

### 23.3 Instructions for using temperature sensor

The temperature (T) is proportional to the sensor voltage output (Vs), so the temperature is calculated as follows:

T = (Vs - V1) / slope + 25°C

T: Measured temperature (°C)

Vs: Output voltage of the temperature sensor at temperature measurement (V)

V1: Voltage output at 25°C measured by temperature sensor (V)

Slope: Temperature slope of the temperature sensors(V/ $^{\circ}$ C), slope = -3.5 mV/ $^{\circ}$ C

Remark: Temperature sensors have low accuracy and are not recommended for use in applications where high accuracy is required.

# **Chapter 24 Option Bytes**

### 24.1 Function of option bytes

Addresses 000C0H~000C3H, 500004H of the flash emory of the CMS32L032 form an option byte area.

Option bytes consist of user option byte (000C0H to 000C2H) and Flash data protection option byte (000C3H, 500004H). When powered on or reset is initiated, the specified function is set with reference to the option byte. When using this product, the following functions must be set by the option byte. For bits that do not have configuration capabilities, you cannot change the initial value.

Notice: Regardless of whether or not to use each function, you must set the option byte.

### 24.1.1 User option bytes (000C0H~000C2H)

#### (1) 000C0H

- Operation of watchdog timer
  - Enable or disable counter operation.
  - Enable or stop counter operation in sleep/deep sleep mode.
- Setting of watchdog timer overflow time
  - Setting of window open period of watchdog timer
- Setting of interval interrupt of watchdog timer
  - Whether or not to use the interval interrupt is selectable.

#### (2) 000C1H

- Setting of LVD operation mode
  - Interrupt & reset mode.
  - Reset mode.
  - Interrupt mode.
  - LVD off (by controlling the externally input reset signal on the RESETB pin)
- Setting of LVD detection level (V<sub>LVDH</sub>, V<sub>LVDL</sub>, V<sub>LVD</sub>)

Notice: When the supply voltage rises, the reset state must be maintained by voltage detection circuits or external resets before the supply voltage reaches the operating voltage range shown in the AC characteristics of the data sheet; When the supply voltage drops, it must be reset by transferring in deep sleep mode, voltage detection circuitry, or external reset before the supply voltage falls below the operating voltage range. The operating voltage range depends on the setting of the user option byte (000C2H).

#### (3) 000C2H

- Setting of the frequency of the high-speed on-chip oscillator
  - Select from 2MHz~32MHz, 48MHz, 64MHz.

### 24.1.2 Flash data protection option bytes (000C3H, 500004H)

Control of flash data protection when debugging on-chip

Level0: Read/write/erase operations on flash data are enabled via debugger.

Level1: Chip erase operations on flash data via debugger are enabled, read/write operations are disabled.

Level2: Operations on flash data via debugger are disabled.

www.mcu.com.cn 608 / 624 Rev.1.0.3

## 24.2 Format of user option bytes

Table 24-1: Format of user option bytes (000C0H)

Address: 000C0H

| WDTINT WII | INDOW1 WIND | OW0 WDTON | WDCS2 | WDCS1 | WDCS0 | WDSTBYON |
|------------|-------------|-----------|-------|-------|-------|----------|
|------------|-------------|-----------|-------|-------|-------|----------|

| WDTINT                            | Interval interrupt of watchdog timer   |  |  |  |  |
|-----------------------------------|--|--|--|--|--|
| 0 Interval interrupt is not used. |  |  |  |  |  |
| 1                                 | When 75% of the overflow time + 1/2F <sub>IL</sub> is reached, an interval interrupt is generated. |  |  |  |  |

| WINDOW1 | WINDOW0 | When watchdog timer window opens |
|---------|---------|----------------------------------|
| 0       | -       | Settings are disabled.           |
| 1       | 0       | 75%                              |
| 1       | 1       | 100%                             |

| WDTON | Controlling counter operation of watchdog timer                        |
|-------|--|
| 0     | Disable counter operation (stop counting after the reset is released). |
| 1     | Enable counter operation (start counting after the reset is released). |

| WDCS2 | WDCS1 | WDCS0 | Overflow time of watchdog timer (F <sub>IL</sub> =20KHz (MAX.)) |  |  |  |
|-------|-------|-------|---|--|--|--|
| 0     | 0 0 0 |       | 2 <sup>6</sup> /F <sub>IL</sub> (3.2ms)                         |  |  |  |
| 0     | 0     | 1     | 2 <sup>7</sup> /F <sub>I</sub> ∟ (6.4ms)                        |  |  |  |
| 0     | 1     | 0     | 2 <sup>8</sup> /F <sub>IL</sub> (12.8ms)                        |  |  |  |
| 0     | 1     | 1     | 2 <sup>9</sup> /F <sub>IL</sub> (25.6ms)                        |  |  |  |
| 1     | 0     | 0     | 2 <sup>11</sup> /F <sub>IL</sub> (102.4ms)                      |  |  |  |
| 1     | 0     | 1     | 2 <sup>13</sup> /F <sub>IL</sub> (409.6ms)                      |  |  |  |
| 1     | 1     | 0     | 2 <sup>14</sup> /F <sub>I</sub> ∟ (819.2ms)                     |  |  |  |
| 1     | 1     | 1     | 2 <sup>16</sup> /F <sub>IL</sub> (3276.8ms)                     |  |  |  |

| WDSTBYON | Counter operation control (sleep mode) of watchdog timer |
|----------|--|
| 0        | In sleep mode, counter operations are stopped.           |
| 1        | In sleep mode, counter operations are enabled.           |

#### Remark:

- 1. When the WDSTBYON bit is "0", regardless of the values of the WINDOW1 bit and the WINDOW0 bit, it is 100% during window opening.
- 2.  $F_{IL}$ : Low-speed on-chip oscillator clock frequency

| _          | _       | Settings other than above are prohibited. |                              |       |       |       |         |         |  |  |  |  |  |  |  |

#### Notice:

1. Bit4 must be written as "1".

2. When the supply voltage rises, the reset state must be maintained by the voltage detection circuit or external reset before the supply voltage reaches the operating voltage range shown in the AC Characteristics of the datasheet; when the supply voltage falls, the reset state must be reset by the transfer of the sleep mode, the voltage detection circuit, or the external reset before the supply voltage falls below the operating voltage range. The operating voltage range depends on the setting of the user option byte (000C2H).

#### Remark:

- 1. X: Ingore
- 2. For details of LVD circuit, please refer to "Chapter 21 Voltage Detection Circuit".
- 3. The detection voltage is a TYP value. For details, please refer to the LVD circuit characteristics in the data sheet.

| Address: 500 | 004H |           |             |              |              |             |          |   |  |  |
| Symbol       | 7    | 6         | 5           | 4            | 3            | 2           | 1        | 0 |  |  |

| OCDM          | OCDEN | Control of flash data protection  |
|---------------|-------|---|
| 3C            | C3    | Manipulation of flash data via debugger is disabled.  |
| Other than 3C | C3    | Chip erase operation on flash data via debugger is enabled, read/write operation is disabled. |
| Other than    | above | Read/write/erase operations on flash data via debugger are enabled.                           |

OCDM[7:0]

Notice: The 50\_0004H address belongs to the data flash memory area. If you use this address for data storage, make sure that the value does not cause missetting of protection options.

www.mcu.com.cn 615 / 624 Rev.1.0.3

# **Chapter 25 FLASH Control**

## 25.1 FLASH control function description

This product contains a 64KByte FLASH memory, which is divided into 128 Sectors, each with a capacity of 512 Bytes. It can be used as program memory and data memory. This module supports erase, program and read operations for this memory.

#### 25.2 Structure of FLASH memory

www.mcu.com.cn 616 / 624 Rev.1.0.3

# 25.3 Registers for controlling FLASH

The registers that control FLASH are as follows:

- Flash write protection register (FLPROT)
- Flash operation control register (FLOPMD1, FLOPMD2)
- Flash erase mode control register (FLERMD)
- Flash status register (FLSTS)
- Flash chip erase time control register (FLCERCNT)
- Flash sector erase time control register (FLSERCNT)
- Flash write time control register (FLPROCNT)
- Flash mode time control register (FLNVSCNT/FLPRVCNT/FLERVCNT)

## 25.3.1 Flash write protection register (FLPROT)

Flash protection register is a register used to protect the FLASH operation control register.

Address: 0x40020020 After reset: 00000000H R/W

| Symbol | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20    | 19   | 18 | 17 | 16  |
|--------|----|----|----|----|----|----|----|----|----|----|----|-------|------|----|----|-----|
| FLPROT | -  | ı  | ı  | 1  | ı  | 1  | ı  | ı  | ı  | ı  | ı  | ı     | -    | -  | -  | -   |
|        | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4     | 3    | 2  | 1  | 0   |
|        | -  | -  | -  | -  | -  | -  | -  | -  |    |    | PF | KEY[7 | ':1] |    |    | WRP |

| WRP | Operation register (FLOPMD1/FLOPMD2) write protection |
|-----|---|
| 0   | Rewriting of FLOPMD1/ FLOPMD2 is not allowed.         |
| 1   | Rewriting of FLOPMD1/ FLOPMD2 is allowed.             |

| PRKEY[7:1]  | WRP write protection |  |  |  |  |  |  |
|---|----------------------|--|--|--|--|--|--|
| 78h Rewriting of WRP is allowed.                  |                      |  |  |  |  |  |  |
| Other than above Rewriting of WRP is not allowed. |                      |  |  |  |  |  |  |

www.mcu.com.cn 617 / 624 Rev.1.0.3

# 25.3.2 FLASH operation control register (FLOPMD1, FLOPMD2)

Flash Operation Control Register is used to set the erase and write operations of FLASH.

| Address: 0x40 | 0020004 | l Afte | r reset: | : 00000 | 0000H I | R/W |    |    |    |    |    |       |          |    |    |    |

## 25.3.3 Flash erase control register (FLERMD)

Flash erase control register is used to set the type of FLASH erase operation.

| Address: 0x | 4002000C | After reset:<br>00H | R/W |       |       |   |   |   |   |
|-------------|----------|---------------------|-----|-------|-------|---|---|---|---|
| Symbol      | 7        | 6                   | 5   | 4     | 3     | 2 | 1 | 0 |   |
| FLERMD      | 0        | 0                   | 0   | ERMD1 | ERMD0 | 0 | 0 | 0 | l |

| ERMD1 | ERMD0 | MANIPULATION                                |
|-------|-------|---|
| 0     | 0     | Sector erase, no hardware check after erase |
| 1     | 0     | Sector erase, hardware check after erase    |
| 0     | 1     | Chip erase Note                             |
| 1     | 1     | Disable settings                            |

Note: Chip erase only erases the code flash area, not the data flash area. And chip erase does not support hardware check.

www.mcu.com.cn 618 / 624 Rev.1.0.3

#### 25.3.4 Flash status register (FLSTS)

The status of the FLASH controller can be queried through the status register.

Address: 0x40020000 After reset: R/W 00H

 Symbol
 7
 6
 5
 4
 3

 EVFNote
 0
 OVFNote

| OVF | FLASH erase/write operation complete flag    |
|-----|--|
| 0   | FLASH erase/write operation is not completed |
| 1   | FLASH erase/write operation is completed     |

Note: The OVF needs to be cleared by writing "1" in software. If it is not cleared, the next erase operation cannot be performed.

| EVF | FLASH erase hardware check error flag         |
|-----|---|
| 0   | No hardware check error after FLASH erase     |
| 1   | Hardware check error occurs after FLASH erase |

Note: EVF needs to be cleared by writing "1" in the software.

#### 25.3.5 Flash chip erase time control register (FLCERCNT)

FLCERCNT register enables to set the FLASH full chip erase time.

Address: 0x40020010 After reset: Undefined R/W

Symbol FLCERCNT

| 31   | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21   | 20      | 19 | 18 | 17 | 16 |
|------|----|----|----|----|----|----|----|----|----|------|---------|----|----|----|----|
| load | -  | -  | -  | -  | -  | -  | -  | -  | -  | -    | -       | ı  | -  | ı  | -  |
| 15   | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5    | 4       | 3  | 2  | 1  | 0  |
| -    | -  | -  | -  | -  | -  |    |    |    | F  | LCER | CNT[9:0 | 0] |    |    |    |

| LOAD | Select erase time <sup>Note</sup>                    |
|------|--|
| 0    | Erase time is set using the hardware                 |
| 1    | Erase time is set using the software (FLCERCNT[9:0]) |

Note: When the master clock is an on-chip high-speed OCO or the external input clock is ≤16M, the hardware setting time can be used without setting FLCERCNT.

| FLCERCNT[9:0]           | Software erase time setting   |
|-------------------------|---|
| Chip erase time = (CERO | CNT*2048*T <sub>FCLK</sub> ), which meets the hardware requirement of >30ms |

www.mcu.com.cn 619 / 624 Rev.1.0.3

#### 25.3.6 Flash sector erase time control register (FLSERCNT)

LSERCNT register enables to set the FLASH full erase time.

Address: 0x40020014 After reset: Undefined R/W

Symbol

FLSERCNT

| 31   | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21   | 20      | 19 | 18 | 17 | 16 |

## 25.3.7 Flash write time control register (FLPROCNT)

FLPROCNT register enables to set the FLASH WORD write time.

Address: 0x4002001C After reset: Undefined R/W

Symbol FLPROCNT

| 31    | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23   | 22   | 21     | 20    | 19    | 18 | 17 | 16 |
|-------|----|----|----|----|----|----|----|------|------|--------|-------|-------|----|----|----|
| Load1 | -  | -  |    |    |    |    |    | FLPG | SCNT | [12:0] |       |       |    |    |    |
| 15    | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7    | 6    | 5      | 4     | 3     | 2  | 1  | 0  |

#### 25.4 How to operate FLASH

#### 25.4.1 Sector erase

The erase time is realized by the hardware or can be configured by FLSERCNT. The operation flow is as follows.

- 1) Set FLERMD.ERMD0 to 1'b0, select the sector erase mode, and set the value of ERMD1 according to whether or not hardware check is required.
- 2) Set FLPROT to 0xF1, unprotect FLOPMD. Then set FLOPMD1 to 0x55, FLOPMD2 to 0xAA, and
- 3) Write arbitrary data to the first address of the erase target sector. Example: \* ((unsigned long \*)0x00000200)=0xfffffff.
- 4) Query the status register FLSTS.OVF through software, when OVF=1, it means the erase operation is completed.
- 5) If hardware check after erase is set (ERMD1=1), you can determine whether the verification is correct by software for FLSTS.EVF.
- 6) Before the next operation, set the software to "1" to clear the FLSTS.

#### 25.4.2 Chip erase

Chip erase, and the erase time are implemented by hardware and can also be configured via FLCERCNT. The operation process is as follows

- 1) Set FLERMD. ERMD0 to 1'b1, and select chip erase mode;
- 2) Set FLPROT to 0xF1 to unprotect FLOPMD. Then set FLOPMD1 to 0x55 and FLOPMD2 to 0xAA
- 3) Write arbitrary data to any address in the flash area of the code.
- 4) Query the status register FLSTS.OVF through software, when OVF=1, it means the erase operation is completed.
  - 5) Before the next operation, set the software to "1" to clear the FLSTS.

#### 25.4.3 Word program

Word programming and write time are implemented by hardware and can also be configured via PROCNT. The operation process is as follows:

- 1) Set FLPROT to 0xF1, unprotect FLOPMD. Then set FLOPMD1 to 0xAA, FLOPMD2 to 0x55, and
- 2) Write the corresponding data to the target address.
- 3) Query the status register FLSTS.OVF through software, when OVF=1, it means the write operation is completed.
  - 4) Before the next operation, set the software to "1" to clear the FLSTS.

#### 25.5 Flash read

The fastest fetch frequency supported by the built-in FLASH is 32 MHz. when the HCLK frequency exceeds 32 MHz, the hardware will insert 1 wait cycle when the CPU accesses the FLASH.

## 25.6 Cautions for FLASH operation

- Flash memory has strict time requirements for the control signal of erasing and programming operation, and the timing of the control signal is not qualified, which will cause the erase operation and programming operation to fail. The setting of the erase and write parameters can be implemented by hardware, or it can be modified by modifying the parameter registers; When using on-chip high-speed OCO, MAINOSC/ external input clock = 16M, it is recommended to use hardware-set erase and write parameters without setting parameter registers.
- If the erase/write operation is executed from FLASH, the CPU stops fetching and the hardware automatically waits for the completion of the operation to proceed to the next instruction. If the operation is executed from RAM, the CPU will not stop fetching and can continue the next instruction.
- If the CPU executes an instruction to enter deep sleep while the FLASH is in programming operation, the system waits for the programming action to end before entering deep sleep.
